Foreword

This report summarizes the activities of Regional and Resident Geologists for 1985, and includes accounts of mining, exploration, and geoscience activities in Ontario, prepared from information collected and filed by the Regional and Resident Geologists. Listings of new additions to the Assessment Files Records, and reports of government survey projects are provided.

Regional and Resident Geologists are located in key centres of the Mining Divisions of the Province to provide geoscience information and advice to the public on the geology and mineral deposits of Ontario. Each office maintains a library of published and unpublished reports, technical papers and monographs, publications of the Ontario Geological Survey and other government agencies, records of exploration activity submitted for assessment work credit, reports of property visits made by the Regional or Resident Geologists' staff, and information received directly from companies and individuals.

A wide variety of mineral resources-related investigations undertaken by regional minerals staff are reported here. These range from geoscience data inventories to technical studies on petroleum resources, building stone, industrial minerals, aggregate resources, and metallic and non-metallic mineral deposits.

Core storage facilities were operative in six centres including Kirkland Lake, Timmins, Sault Ste. Marie, Bancroft, Tweed, and Thunder Bay. A core collection and cataloguing program developed by the Resident Geologists' staff at these centres has been highly successful, ensuring that as much as possible of the available diamond-drill core is collected and stored.

W. Meyer became Resident Geologist at Sudbury, subsequent to the resignation of J.M. Martins; and R.A. Trevail, Chief Geologist, Petroleum Resources Laboratory, assumed the responsibilities of Regional Geologist, London.

INTRODUCTION

Current permanent staff in the Resident Geologist's office includes C.E. Blackburn, Resident Geologist, and M.R. Hailstone, Resource Geologist. Contract staff during 1985 comprised the following people: Dolores Danielson, Susan Turner, and Sheri Rowan, clerk-typists; C.C. Storey commenced duties as Drill Core Library Geologist, assisted by C.B. Ravnaas; J. Parker, funded by the Ontario Ministry of Northern Development and Mines, continued an Economic Geologist program in the general Dryden-Ignace area, assisted by R. Schienbein; M. Patterson, funded by the Ontario Ministry of Northern Development and Mines, prepared Geological Data Inventory Folios.

RESIDENT GEOLOGIST STAFF ACTIVITIES

The continued progress of Nuinsco Resources Limited's gold exploration and advanced evaluation at Cameron and Rowan Lakes was monitored throughout 1985 by numerous on-site visits and contacts with company personnel. Of the properties at an advanced stage at the end of 1984, those of Nuinsco were the only ones that remained active throughout 1985. Numerous properties and areas undergoing active exploration were visited. These are: the Abraham Occurrence and associated Neda vein near Sioux Narrows, under evaluation by McManus Red Lake Mines; Lynx-Canada Explorations Limited's and Sparton Resources Incorporated's gold joint venture in the Bennett Lake area; Canadian Nickel Company Limited's option on the old Virginia Mine in the Atikwa Lake area; Kidd Creek Mines Limited's option on A. Kozowy's gold prospect at Flambeau Lake, Aubrey and Van Horne Townships; Cleyo Resources Incorporated's Golden Star and Isabella Mine properties near Vine Centre, under evaluation by David Bell and Associates; Corporation Falconbridge Copper's option from R.W. Fairservice of his gold property at the south end of the Lawrence Lake Batholith, in the Bluffpoint Lake area; evaluation for Kenora Prospectors and Miners Limited of the eastward extension of the old Cornucopia Mine workings at Bag Bay of Shoal Lake; Kennco Explorations (Canada) Limited's drill program at the old Scramble Mine in Jaffray Township under option from Boise Cascade Canada Limited; the exploration by Homestake Mineral Development Company along the Crowduck Lake-Rush Bay Lineament, Lake of the Woods, including their option on the Nor-Penn gold occurrence from Academy Explorations Limited; the option of B.P. Canada Incorporated (Selco Division) from R.W. Fairservice on the Thrasher gold prospect in the Lobstick Bay area; Sparton Resources Incorporated's gold exploration at Manitou Stretch in the Napanee Lake area; Kidd Creek Mines Limited's options on the old Gold Hill, Black Jack, and Golden Gate Prospects in the Bigstone Bay area, Lake of the Woods; and Corporation Falconbridge Copper's option on the McKenzie-Gray Occurrence in the Bad Vermilion Lake area. Other prospects under evaluation, and inactive mineral showings were examined and reported on during the year. The Kenora Resident Geologist area is shown in Figure 1.1.

A major undertaking that came to fruition in the Spring was the hosting of the 31st Annual Institute on Lake Superior Geology in Kenora, May 6-11, 1985. The meeting was organized by the staff of the Resident Geologist's office, Kenora, with major cooperation from the Precambrian and Mineral Deposits Sections of the Ontario Geological Survey. A total of 243 people registered for the conference, including professional geologists and students from Canada and the U.S.A. The program consisted of three pre-meeting and three post-meeting field trips, and two days of technical papers. Field trips, discussed in detail in the Field Trip Guidebook (Beakhouse 1985), were designed to give an overview of Precambrian geology and mineral deposits within Kenora Mining Division, and covered the following topics: geologic setting and style of gold mineralization in the Lake of the Woods area, including a side trip to Nuinsco Resources Limited's Cameron Lake gold property; geologic relationships in the vicinity of the Wabigoon-Winnipeg River subprovincial boundary near Kenora; interpretation of volcanic facies in the Berry River Formation, near Sioux Narrows; and granitoid related mineralization in the Dryden area.

At the technical session, 58 papers were presented, both orally and as posters, covering geological topics in both the northern states of the U.S.A., and in Ontario and Manitoba. Abstracts were published in an Abstracts volume (Blackburn 1985)

Geoscience lectures and field trips were provided for Rough Rock and Gelley Lake Junior Ranger Camps, local schools, and a manpower training course. Liaison was maintained with Ontario Geological Survey field parties. J. Parker, Economic Geologist, presented a very successful prospecting course at Dryden, in 10 weekly evening sessions, and a field trip. Average attendance was 60 people.

MINING ACTIVITY

Following expenditures in 1984 in the $5 million range at the Duport Mine gold property of Consolidated Professor Mines Limited by Union Carbide Exploration Corporation, no further work was carried out by that company in 1985.

• Exploration Activities in 1985 (keyed to table 3)

▭ Extent of contiguous staking to Dec 1, 1985 (may include patented claims in areas of intense staking)

+ Isolated active claim blocks as of Dec 1, 1985

Based on results of the 1984 program, Consolidated Professor released recalculated reserve figures in mid-1985 (The Northern Miner, June 6, 1985). The new figures are 1 445 235 tons grading 0.33 ounce gold per ton across an average mining width of 9 feet. This includes proven reserves of 132 000 tons grading 0.41 ounce gold per ton across a width of 8.97 feet, and probable reserves of 556 742 tons grading 0.34 ounce per ton across 10.59 feet. These figures compare with previous estimates of 1 927 000 tons grading 0.3 ounce per ton released by Union Carbide following their surface exploration program in 1983, and prior to the underground development. Reduced tonnage estimates in the East zone, where reserves now stand at 397 000 tons grading 0.38 ounce gold per ton, were cited as a reason for the overall reduction in tonnage outlined. This reduction in tonnage in the East zone was compensated by the underground program exposing several zones of higher than average grade material in the Main zone, according to the Northern Miner article: in the north drift on the 440-foot level, a grade of 0.6 ounce gold per ton was assayed along 331 feet, for a width of 9.5 feet, widening to 25 feet in places.

The Northern Miner article also revealed that Union Carbide spent $4.5 million on the project in 1984, funding 3600 feet of access ramp and crosscuts, 2100 of drifting, and 21 740 feet of drilling. Also 6000 tons of development muck, which is stockpiled on surface, was mined, and a bulk smple of 2000 tons returned an assay of 0.31 ounce gold per ton.

In November, Consolidated Professor announced that Union Carbide had made a payment of $500 000 to continue its participation in the joint venture, and has until November 1, 1986, to make a commitment to bring the property to production.

G.R. Cunningham-Dunlop, President, Consolidated Professor Mines Limited (personal communication, November 1985) confirms that, following relogging of all 1984 drill core and assaying of 200 extra samples, A.C. Troop, consultant for Consolidated Professor, has newly calculated reserves to be in the l.4 million tons range, at a grade of 0.32 ounce gold per ton.

Following initial establishment of a small milling operation in the Mine Centre area in 1984, in which a 75 ton per day mill was placed on site at the Manhattan Prospect by Royal Gold and Silver Corporation in their Mine Centre Gold venture with Oro Treck Resources Corporation, operations wound down early in 1985.

Federal Kirkland Mines indicated (The Northern Miner, June 20, 1985) their intention to recover gold from tailings near Mine Centre. A centrifugal mill was located near the old Golden Star Mine in the Bad Vermilion Lake area.

QUARRYING ACTIVITY

DIMENSION STONE

Three dimension stone quarries, viz. Granite Quarriers (GQI) Incorporated, Nelson Granite Limited, and Rush Bay Quarries, operated during the year. Nelson Granite Limited and Granite Quarriers (GQI) Incorporated produce pink granite for monuments and for building construction from a small granite stock 9 km west of the town of Vermilion Bay. Production from both quarries increased over 1984 levels. Granite Quarriers is installing a replacement hoist and has additional mobile equipment in use at the quarry. Nelson Granite Limited is now operating a small finishing plant at the quarry site to produce monuments, curbing, and sales samples. One hundred metres of curbing made by Nelson Granite was installed on Whyte Avenue in the Town of Dryden in 1985.

Flagstone was quarried by Rush Bay Quarries from a sheared felsic tuff deposit in Forgie Township. This stone is green to dark grey in colour on the fresh surface, with rusty brown shades on the foliation surface due to ground water action. The surface colour varies from light brown to dark red, the dark red being most desirable.

A quarry permit to remove soapstone from the dump at the Eagle Lake soapstone quarry was issued to Frank Thorgrimson of Keewatin.

CRUSHED STONE

Crushed stone was produced in large quantities by Canadian National Railways (C.N.R.) at White in Rice Township and Canadian Pacific Railways (C.P.R.) at Hawk Lake in MacNicol Township and Melgund Lake in Avery Township. Material is quarried and crushed by a contractor and stockpiled at the quarry site for use as required for roadbed maintenance and repair. The C.P.R. quarry at Hawk Lake did not produce new crushed stone, but material was removed from the stockpile and some of the undersize material was screened and sold for local construction use. The railway ballast quarries are the largest bedrock producers and are responsible for the vast majority of the yearly production of stone of all kinds, which ranges from 500 000 to 900 000 tonnes within the Kenora Legislative District (figures are from Ontario Mineral Score 1981, 1982, 1983, 1984).

Approximately l64 475 m^3 (215 000 cubic yards) was produced from the C.N.R. White quarry. Production data for the C.P.R. quarry is not yet available.

Several companies operated bedrock quarries for crushed stone for aggregate, road construction, and similar uses; these include Degagne Brothers Limited in Jaffray Township, George Kupper Contracting Limited in Mutrie Township, Towland-Hewitson Construction in Jaffray Township, and Eino Stenburg in Britton Township. Two other quarries were operated in Redditt Township near Redditt, one for rock fill and one for aggregate for the reconstruction of Highway 658. Figure 1.3 shows the locations of quarrying activity.

PEAT AND BLACK SOIL

Ten quarries producing peat or black soil were active. Small amounts of peat for horticultural use were produced by Arctic Peat Moss Limited of Barwick, from a bog in Carpenter Township. The company has two processing plants in Barwick, one for baled peat and one for top moss, the unhumified top layer of the bog sold for plant bedding, packing, and similar horticultural uses. Only top moss was produced during 1985. Du-Nor Products of Fort Frances processes well hu-

*to Nov. 30

mified peat for use as potting soil. During the early part of 1985, production was from a site within the town of Fort Frances. The company is preparing to open a bog in Miscampbell Township and has a plant in Fort Frances, but is not presently operating. Nu-Terra Limited of Kenora produces similar soil from a peat deposit in Jaffray Township near Kenora. Black soil, or well humified peat for use in landscaping, is produced by several contractors, and quarry permits for its removal were issued or renewed for seven sites.

GRAVEL

A total of 243 quarry permits were issued for sand and gravel extraction from Crown Land. The largest users of gravel, as shown by numbers of permits, are the forest products companies for road construction and maintenance. Municipalites, Ministry of Transportation and Communications, contractors, and private users account for the rest. Many contractors own or lease gravel pits on private land where quarry permits are not required. The number of these pits is not presently recorded. Three permits were issued for the removal of large boulders for unspecified uses.

EXPLORATION ACTIVITY

Data in Table 1.1 indicate that exploration for gold in Kenora Mining Division in 1985 continued at the high level set in 1984, when measured in terms of man days of assessment work on mining claims (but less than 300 000 compared with 364 672 in 1984). Although staking activity was down somewhat compared with 1984 (2000-plus claims against 3261 in 1984), while cancellations were up sharply (more than 5000, compared with 3042 in 1984), the number of active claims remained high, at about 11 000. While the gold price remained low compared to the 1983 high of around $500 per ounce, its stability at about the $320 to $340 per ounce level probably contributed to this continuing favourable situation.

Tables 1.3 and 1.4 list the exploration activity during the year and the assessment work and other information received.

TABLE 1.4 **ASSESSMENT WORK AND OTHER INFORMATION RECEIVED.**

KENORA MINING DIVISION

SYMBOLS AND ABBREVIATIONS

AMag	- Airborne Magnetometer Survey	EM	- Electromagnetic Survey	Pb	- Lead
AEM	- Airborne Electromagnetic Survey	Expend	- Expenditure Credits	Pt	- Platinum
Ag	- Silver	Geochem	- Geochemical Survey	Rad	- Radiometric Survey
Assess	- Assessment Work	GL	- Geological Survey or Report	SA	- Sampling, Assaying
Au	- Gold	HEM	- Horizontal Loop Electromagnetic Survey	Sb	- Antimony
BM	- Base Metals	IP	- Induced Polarization	Seism	- Seismic Geophysical
Cons Rpt	- Consultant's Report	Mag	- Magnetometer Survey	Sn	- Tin
Co	- Cobalt	Man	- Manual Work	SP	- Self Potential
Cu	- Copper	Mech	- Mechanical	STr	- Stripping
DD	- Diamond Drilling (where shown, the number following "DD" indicates the number of holes drilled and the total length drilled respectively)	Mo	- Molybdenum	Ti	- Titanium
		Ni	- Nickel	Tr	- Trenching
		OMEP	- Ontario Mineral Exploration Program	W	- Tungsten
				Zn	- Zinc

The majority of exploration was directed at the Kakagi-Rowan Lakes area, where activity continued to be high at Nuinsco Resources Limited's Cameron and Rowan Lake Properties. The Manitou Lakes area, scene of a major exploration push by Teck Corporation, among others, in 1984, was not as active in 1985. Other areas of activity included northern Lake of the Woods, the Straw Lake area, Eagle, Wabigoon, and Kawashegamuk Lakes, the Mine Centre area, and Bee Lake in northwestern corner of the Division (Table 1.3).

Exploration for base metals continued, notably by one company only, Corporation Falconbridge Copper, at Rainy River. Interest in platinum-group elements and chromite was noted, but no concerted exploration programs were mounted. Interest in titanium near Mine Centre continued.

GOLD

Kakagi–Rowan Lakes Area

Nuinsco Resources Limited continued to run its exploration venture at Cameron and Rowan Lakes throughout 1985. Commenced in 1981 at Cameron Lake, with a period of relative inactivity in 1982, and acquisition of its Rowan Lake Monte Cristo holdings in 1983, activity of that company precipitated a staking rush in that year. The year 1984 saw major activity on both the Cameron Lake and Rowan Lake holdings, with exploration of the new Victor zone at that time. At Cameron Lake, ore reserves were estimated to be between 1.5 and 2 million tons grading 0.15 to 0.2 ounce gold per ton.

Early in 1985, Nuinsco entered into an agreement with Echo Bay Mines Limited in which the latter was to contribute $350 000 in the purchase of shares, and to undertake to spend $1 million in 1985 on exploration, and the right to spend a further $3 million by purchase of shares. This substantial commitment of funding enabled Nuinsco to proceed with

diamond drilling programs on both its Cameron Lake and Rowan Lake Properties throughout 1985. By March, the winter drill program at Rowan Lake had led to the announcement (The Northern Miner, March 28, 1985) of an intersection of 17.3 feet grading 0.37 ounce gold, including an 11-foot section grading 0.56 ounce gold, on the new Victor zone.

Echo Bay's continuing interest in the area was indicated by its entering into an agreement with Inco in exploration of the latter company's ground immediately west of Nuinsco's Cameron Lake holdings.

In May, Nuinsco announced (The Northern Miner, May 16, 1985) new calculations of reserves in the Main zone of 1 328 000 tons grading 0.16 ounce gold per ton, to a depth of 1100 feet, including a core of 900 000 tons grading 0.20 ounce per ton.

By July, 20 000 feet of new drilling on the Main zone was completed (The Northern Miner, August 22, 1985), increasing reserve calculations to 1 625 000 tons grading 0.16 ounce gold per ton, to a depth of 1100 feet, of which 1 000 000 tons grades 0.23 ounce gold per ton. An Interim Report to shareholders, issued November 29, 1985, indicates that in total 17 shallow holes were diamond drilled on the Victor zone during the 1985 season, tracing the zone from surface to a depth of about 700 feet, and indicating about 300 000 tons grading about 0.12 ounce gold.

Nuinsco's interests along the so-called Monte Cristo shear zone were increased by its entry into a joint venture with Charger Resources Limited on the latter company's ground to the west of Nuinsco's Rowan Lake holdings.

By the end of September, Echo Bay Mines Limited had made a decision to defer underground exploration on the Main zone at Cameron Lake by providing a further $1.5 million for exploration on Nuinsco property. Echo Bay also entered into an agreement with Canolan Resources Limited, on the latter company's 32-claim block situated between Cameron and Rowan Lakes.

Construction of a 12-mile long access road to Cameron Lake from Highway 71 proceeded during the late summer and fall of 1985, and was completed before year's end.

The exploration activity on properties surrounding those of Nuinsco, initiated in 1984 as a result of the staking rush of 1983 at Kakagi-Rowan Lakes, continued into 1985. Some of these properties are on strike with or closely parallel to either the Cameron Lake Property or the Monte Cristo and Victor Island Prospects of Nuinsco. In 1984, the following of these companies were particularly active (Blackburn and Hailstone 1985, p.8-9): Bigstone Minerals Limited; Charger Resources Limited; Dejour Mines Limited; Del Norte Chrome Corporation; Falcon Resources Incorporated; and Canolan Resources Limited. However, exploration was continued only on the property of Del Norte Chrome in 1985, and D.K. Platinum Corporation became active in addition to those listed above.

Silver Lake Resources Incorporated, in its 50-50 joint venture with Del Norte Chrome on the latter's ground, conducted in the late winter of 1984-85, 2400 feet of diamond drilling over three holes (The Northern Miner, March 21, 1985), directed at magnetic features, beneath Sullivan Bay of Rowan Lake. Subsequent assay information (Assessment Files, Resident Geologist's Office, Kenora) indicates values in the range of trace to 0.008 ounce gold per ton were obtained. However, a number of shears were intersected that suggest the Monte Cristo-Victor Island shear zone does extend southwestward beneath the waters of Sullivan Bay.

D.K. Platinum Corporation carried out geological mapping and ground electromagnetic and magnetic surveys between May and August of 1985 over 49 claims at the eastern end of the Nolan Lake stock, subsequent to an airborne electromagnetic and magnetic survey flown late in 1984 (Assessment Files, Resident Geologist's Office, Kenora). Offset, east-trending conductors are interpreted by C.J. Kuryliw, consultant for D.K. Platinum, to represent shear zones displaced by northerly trending faults (Assessment Files, Resident Geologist's Office, Kenora, and personal communication). Mr. Kuryliw suggests these shears to be good targets for diamond drilling.

Elsewhere in the general Kakagi-Rowan Lakes greenstone belt, a number of companies continued exploration commenced in previous years. Canadian Nickel, as operator in a joint venture with Welcome North Mines Limited, diamond drilled two 1000 m long alteration zones associated with differentiated mafic to ultramafic sills at the Penn Prospect on Kakagi Lake. This was carried out as follow-up to geophysical surveys and geological mapping in 1984 (Assessment Files, Resident Geologist's Office, Kenora).

Falconbridge Limited diamond drilled four holes in 1985 at Cedartree Lake in the Dogpaw Lake area, following the drilling of 22 holes on their McLennan Prospect option from Welcome North in 1984 (R. Band, Geologist, Falconbridge, Winnipeg, personal communication, 1985).

Dubenski Gold Mines Limited continued a diamond drill program on the Caswell-Williams (or Dubenski) Prospect at Flint Lake (J.P. Sheridan, consulting engineer, personal communication, 1985).

Cymbal Explorations Incorporated carried out a basal till survey on their Young Bay gold property, Kakagi Lake, in March, 1985, as follow-up to geological and geophysical surveys performed in 1983 and 1984 (Assessment Files, Resident Geologist's Office, Kenora). This survey, drilled under Young Bay, represents one of the few basal till surveys using a sonic drill carried out in the Kenora Mining Division.

B.P. Resources Canada Limited continued work on their Lobstick Bay option from R.J. Fairservice, with ground magnetic, electromagnetic, and induced polarization surveys, and diamond drilling, reportedly one hole (Assessment Files, Resident Geologist's Office, Kenora), carried out as a follow-up to geological mapping and sampling done in 1984. This property, on the northern shore of Lobstick Bay, had previously been under option to Esso Minerals Canada. B.P. Resources Canada Limited also performed diamond drilling, reportedly two holes (Assessment Files, Resident Geologist's Office, Kenora), on their Mushkasu Lake option, also from R.J. Fairservice. This property had previously been under option to Noranda Incorporated.

Exploration was newly commenced on a number of properties in the general Kakagi-Rowan Lakes area in 1985. Fort Knox Gold Resources reported (The Northern Miner, March 28, 1985) on three diamond-drill holes at the old Virginia Mine in the Atikwa Lake area, carried out by Inco Limited as operator. Stripping and trenching were carried out over the summer, and short Winkie drillholes were used to undercut surface trenches.

New McManus Red Lake Gold Mines Limited, in a joint venture with Lodi Metals Incorporated, carried out diamond drilling at the old Regina Mine near Sioux Narrows (George Cross News Letter, April 11, 1985). Drilling was conducted both on the Regina Mine veins, and on the Neda vein.

Geophysical surveys, both airborne and on the ground, were conducted by, or on behalf of, the following companies and individuals: in the Rowan Lake area, by Great Central Mines Limited, by Lear Oil and Gas Corporation, by Loydex Resources Incorporated, by V. Regan, and by Canolan Resources Limited; in the Atikwa Lake area, by Cominco Limited; in the Dogpaw Lake area, by K. Kriese, by Proteus Resources Limited, and by Bigstone Minerals Limited; in the Heronry and Dogpaw Lakes areas, by Canadian Nickel Company Limited; in the Rowan and Atikwa Lakes areas, by J. Hansen; and in the Lawrence and Tadpole Lakes area, by Campbell Resources Incorporated.

Other work known to have been performed includes: geological surveys, in the Dogpaw Lake area by Dunfrazier Gold Exploration Incorporated and by Proteus Resources Limited, and in the Rowan Lake area by J.F. O'Donnell and by V. Regan; diamond drilling in the Rowan Lake area by Sault Meadows Energy Corporation; and work by Maybrun Mines Limited and by Voyager Explorations Limited.

Straw Lake Area

Corporation Falconbridge Copper carried out mapping, lithogeochemical and soil geochemical surveys, induced polarization and magnetic geophysical surveys, stripping and sampling and a five hole drill program on their option from R.W. Fairservice in the Bluffpoint Lake area (Assessment Files, Resident Geologist's Office, Kenora). This property has been under investigation since 1981, firstly by Selco Incorporated, secondly by Noranda Mines Limited, and since 1985 by Corporation Falconbridge Copper.

Sparton Resources Incorporated conducted an eight hole diamond drill program on their Peep and Sorry Mac claim blocks at Manitou Stretch, Napanee Lake area, as follow-up to earlier geological mapping, VLF electromagnetic and magnetic surveys, and lithogeochemical and soil geochemical surveys (Assessment Files, Resident Geologist's Office, Kenora).

Other work known to have been performed includes a geophysical survey by Black Gold Oil and Gas Limited, in the Napanee Lake area, and VLF electromagnetic, magnetic, and geologic mapping surveys, and sampling, carried out by Jack Bolen (personal communication) on his claims between Sullivan and Straw Lakes in the Bluffpoint Lake area.

Manitou–Wabigoon–Eagle Lakes Area

Following a protracted exploration program at Manitou Island, Lower Manitou Lake during 1983 and 1984, Teck Corporation was inactive on the property in 1985. However, following ground geophysical surveys performed in 1984 on their claims east of Jackfish Bay on Upper Manitou Lake, Teck conducted trenching and detailed geological mapping in the fall of 1985 (R.J. Wright, Assessment Files, Resident Geologist's Office, Kenora).

Cochrane Oil and Gas Limited conducted geological and geophysical surveys in the Lower Manitou, Harper, and Boyer Lakes areas in the early part of 1985, following extensive geophysical, geological, geochemical, and diamond drill programs in 1983 and 1984.

Jalna Resources Limited conducted airborne electromagnetic and magnetometer surveys over their 626 claim, 32 km (20 mile) long block in the general Manitou Lakes area during 1985, following extensive work on the ground commencing in 1983, with additional work in 1984. Jalna conducted an airborne geophysical survey over a newly acquired contiguous block of 33 claims, previously held by Voyager Explorations Limited, immediately south of Snake Bay of Stormy Lake, in the Kawashegamuk Lake area. Jalna also flew an airborne geophysical survey over a block of 37 contiguous claims northwest of Gardnar and Beartrack Lakes, Laval Township (Assessment Files, Resident Geologist's Office, Kenora).

June Resources Incorporated flew airborne electromagnetic and magnetometer surveys over two separate claim blocks totaling 104 claims, in the Boyer Lake and Turtlepond Lake areas (Assessment Files, Resident Geologist's Office, Kenora).

Esso Resources Canada Limited, following a diamond drill program of 23 holes totaling 1035 m (3396 feet) at 3 separate showings on their Snake Bay Prospect in the Kawashegamuk Lake area (Assessment Files, Resident Geologist's Office, Kenora), was inactive on the property during 1985.

Sulpetro Minerals Limited began a diamond drill program in late 1985 on their property north of Tabor Lake, Melgund Township. The first hole tested a mineralized quartz-porphyry dike and was drilled to a depth of 108.8 m (357 feet) (Assessment Files, Resident Geologist's Office, Kenora).

Raleigh Resources Limited diamond drilled 7 holes totaling 915 m (3001 feet) on their Fornieri Bay Property on Eagle Lake during the spring of 1985. The drilling followed self-potential geophysical surveys and an 11 hole diamond drill program in 1983 and 1984, which had outlined anomalous gold mineralization (Assessment Files, Resident Geologist's Office, Kenora).

Greenstone Resources Limited conducted ground magnetometer and VLF electromagnetic surveys over eight contiguous claims at the south end of Meridian Bay on Eagle Lake, during the early part of 1985 (Assessment Files, Resident Geologist's Office, Kenora).

Jonpol Explorations Limited, in a joint venture with Beaufield Resources, hold 113 contiguous claims in the Eagle Lake area which have a number

of known gold occurrences (The Northern Miner, August 8, 1985), including the Manhattan Occurrence, conducted prospecting in 1985 (The Northern Miner, September 16, 1985) as follow-up to airborne VLF electromagnetic and magnetometer surveys performed in 1984 (Assessment Files, Resident Geologist's Office, Kenora).

Rio Algom Exploration Incorporated conducted linecutting and ground VLF electromagnetic, total field magnetometer, and horizontal loop max-min surveys on 54 contiguous claims located immediately north of the Trans-Canada Highway in central Bridges Township. Previous work on the property in 1969 by Noranda Mines Limited consisted of geophysical surveys and diamond drilling (Assessment Files, Resident Geologist's Office, Kenora).

Other companies known to have done exploration for gold in the general Manitou-Wabigoon-Eagle Lakes area in 1985 include: an airborne geophysical survey by Beved Resources Incorporated in the Boyer Lake area; a geological survey by Billiton Canada Limited in Laval Township; geological and geophysical surveys done by Gold Washe Limited in the Boyer Lake area; a geophysical survey by Green River Resources Limited in the Turtlepond Lake area; a geophysical survey done by E.M. Hall in the Boyer Lake area; stripping, sampling, and geologic mapping by Kidd Creek Mines Limited in the Contact Bay area; airborne geophysical surveys by Marge Enterprises Limited in the Turtlepond Lake area; airborne geophysical surveys by Marlet Resources Limited in the Boyer Lake area; and an airborne geophysical survey done by Voyager Explorations Limited over ground under option from A. Kozowy in the Wapageisi Lake area.

Lake of the Woods–Shoal Lake Area

Following detailed mapping, geochemical, and geophysical surveys, and surface stripping on Boise Cascade Canada's wholly-owned Scramble Prospect and adjacent unpatented claims, all in Jaffray Township, in 1984, Kennco Explorations entered into an option agreement with the property owner in 1985. Diamond drilling was carried out on the zone containing the Scramble Prospect.

Homestake Mineral Development commissioned an airborne magnetic gradiometer and VLF electromagnetic survey, flown in April 1985, along the east-trending Crow Duck Lake-Rush Bay lineament, northern Lake of the Woods. The area covered is approximately 40 km (25 miles) long by 3 km (2 miles) wide, and an additional contiguous 23-claim block over the eastern end of the Canoe Lake Stock, under option from M.S. Morrison (Assessment Files, Resident Geologist's Office, Kenora). Subsequent reconnaissance geological mapping was carried out over the area in the summer of 1985, and special attention paid to the Nor-Penn Occurrence in the Clearwater Bay area, under option from Academy Explorations Limited.

Kenora Prospectors and Miners, a company that holds patented ground in the Shoal Lake area which includes the past-producing Mikado and Cedar Island (Cornucopia) Mines among other gold prospects, announced in November (The Northern Miner, November 4, 1985) that St. Joe Canada Incorporated had entered into an agreement whereby the latter company, by spending $2.45 million on exploration over the next 4 years, and making cash payments, can earn a 50% interest. Geological work had previously been carried out on Kenora Prospectors and Miners' ground over the summer months.

Exploration commenced in 1983 by Barrier Reef Resources Limited, on a property near High Lake held under option by its subsidiary company Falcon Resources Limited, was continued in 1985. The earlier work consisted of geological, geophysical, and geochemical surveys in 1983 and 1984. The property includes the Electrum Prospect, held under lease by R. Longe. In 1985, work consisted of magnetometer and VLF electromagnetic surveys conducted on one claim only, in the name of Gladys Anne Stephens, over the western end of Electrum Lake.

Mistango Consolidated Resources Limited announced (The Northern Miner, September 16, 1985) that a 3000-foot drill program was scheduled near the former Triggs Mine Prospect in Code Township, and that drilling would also be carried out on a nearby property close to Witch Bay. C. Kuryliw, consultant on the project (personal communication, 1985) confirmed that 3091 feet of diamond drilling was carried out over eight holes, four on the Triggs Prospect, and four on the Witch Bay Property, which he interprets to be the along-strike extension of the Wendigo Mine vein.

Other gold exploration known to have been carried out in the Lake of the Woods-Shoal Lake area in 1985 included: a geological survey by D. Busch in Ewart Township; stripping, and geological and geophysical surveys in the name of G. Clark in Haycock Township; geological and geophysical surveys by J. Hansen in Glass Township; geological and geophysical surveys by W.C. Hood in Kirkup Township; geological and geophysical surveys by W.T. Knox in Code Township; manual work by E. Roberecki in the Bigstone Bay area and in Manross Township; manual work by 553215 Ontario Limited in Jaffray Township; and work by Kidd Creek Mines Limited.

Mine Centre Area

Cleyo Resources Incorporated, under an option agreement with P.I.R.P. Holdings Incorporated, continued an exploration program commenced in 1984 on the Golden Star, Isabella and other occurrences, all south of Mine Centre in the Bad Vermilion Lake area. David R. Bell Geological Services Incorporated, as consultants, carried out a geological, geophysical, stripping, sampling, and diamond drill program (S. Ciglen, Cleyo Resources, personal communication, 1985).

Corporation Falconbridge Copper conducted a stripping, sampling, and a 400 m drill program on the McKenzie Gray Property, optioned from S. Lakatos and K. McTavish in the Bad Vermilion Lake area (G. Riverin, Corporation Falconbridge Copper, personal communication, 1985).

Sparton Resources Incorporated and Lynx-Canada Explorations Limited, in a 50-50 joint venture, carried out approximately 1500 feet of diamond drilling over four holes, all on patented claims and ap-

proximately 300 m west of the Independence Mine in the Bennett Lake area (R. Crowley, Spartan Resources, personal communication, 1985).

Homestake Explorations Limited, a Harbinson Group company, following diamond drilling on their Olive Mine prospect in 1984, announced in 1985 (The Northern Miner, July 18, 1985) that they had oulined 21 000 tons of proven and probable reserves grading 0.24 ounce gold per ton, and another 2300 tons at 0.16 ounce gold per ton, all to a depth of 300 feet, and within the old mine workings. Work in 1985 consisted of a geological mapping and sampling program on Harbinson Group's Stellar and Barber Lake Properties in the Bad Vermilion Lake area.

Other activity known to have been carried out for gold near to Mine Centre during 1985 included: stripping and mechanical work by D. Kroocmo in the Factor Lake area, and a magnetometer survey by J.W. Redden in the Bennett Lake area.

The majority of exploration for gold in the general Fort Frances area was carried out near to Mine Centre. However, one program was carried out northwest of Fort Frances, where Agassiz Resources Limited conducted VLF electromagnetic and magnetic surveys, and geological and sampling programs in the Menary Township and Beadle Lake areas (Assessment Files, Resident Geologist's Office, Kenora).

Bee Lake Area

Following acquisition of a large block of claims adjacent to the Ontario-Manitoba border in 1984, and subsequent prospecting and reconnaissance geological mapping, Maralgo Mines Limited were inactive in the area in 1985. Also in 1984, Noranda Exploration Company Limited had conducted geological and humus geochemical surveys in the vicinity of Anderson, Odd, and Rickaby Lakes (Assessment Files, Resident Geologist's Office, Kenora), but no further work was carried out in 1985.

A group called the Bee Lake Syndicate, in the name of David J. Busch, conducted magnetometer and VLF electromagnetic surveys over the former Mamen Group (or Bee Lake Mines Limited) claims, between Rickaby and Bee Lake (Assessment Files, Resident Geologist's Office, Kenora). Gold is associated with magnetite iron formation on this property.

BASE METALS

The regional exploration program conducted by Noranda Exploration Company Limited within the English River Subprovince, between Highway 105 and the Ontario-Manitoba border, since about 1980, was inactive in 1985. Subsequent to ground work on claims in the vicinity of Oak Lake in 1984, conducted as follow-up to regional airborne geophysical surveys, most of these holdings have subsequently been allowed to lapse. At the present time, Noranda holds only a few small isolated claim blocks in that portion of the English River Subprovince within Kenora Mining Division that was covered by the airborne survey.

Corporation Falconbridge Copper continued their base metal exploration program commenced in 1984 east of Fort Frances. Geological mapping, lithogeochemical and geophysical surveys, and a diamond drill program were all conducted on a large block of claims between Windy Point, south of Swell Bay, and Lochart Lake, situated in Halkirk and Farrington Townships (G. Riverin, Corporation Falconbridge Copper, personal communication, 1985).

Exploration for zinc mineralization, conducted in 1983 and 1984, by Agassiz Resources Limited near Burditt Lake northwest of Fort Frances in Senn and Menary Townships (Assessment Files, Resident Geologist's Office, Kenora) was not continued in 1985; instead, Agassiz's attention turned to gold in the same area, at Off Lake (*see* "Mine Centre Area").

A. Glatz conducted ground magnetometer and VLF electromagnetic surveys over his lead-copper-zinc property south of Rafter Lake in Laval Township east of Dryden, following previous geological work done in 1984 (Assessment Files, Resident Geologist's Office, Kenora).

Sparton Resources Incorporated conducted a geological survey over a zinc-gold occurrence at the east end of Umfreville Lake, in the Paterson Lake area. Known as the Oneman Lake Occurrence, the former name of Umfreville Lake, a previous report on the property was prepared in 1948 by Robert Thomson, then Resident Geologist, Kenora (Assessment Files, Resident Geologist's Office, Kenora).

OTHER MINERALS

Titan Titanium International, a subsidiary of Barron Hunter Hargrave, has outlined from drilling conducted on its Bad Vermilion Lake titanium property prior to 1985, a total indicated reserve of 1 270 000 tons grading 15% titanium dioxide and 45% iron, according to an announcement in the Northern Miner, June 27, 1985. According to the same article, mineralization has been traced to 200 feet depth, and still open below that. The company also maintains (The Northern Miner, August 15, 1985) that without further exploration the property has potential for 177 800 tons of titanium sponge. During 1985, 13 holes totaling 4174 feet, were diamond drilled, and magnetic geophysical surveys carried out on the property (J. Londry, consultant geologist, personal communication, 1985). Of the block of 45 claims, 24 had been brought to lease at time of writing.

Agassiz Resources Limited conducted geological mapping and sampling at a stibnite occurrence at Manitou Stretch, in the Napanee Lake area, initially discovered in the early 1940s by F. Austin. Its gold potential was investigated by Noranda Exploration Company Limited in 1984. The current work appears to indicate that it is primarily an antimony occurrence, with grab samples assaying up to 20 000 ppm antimony (Assessment Files, Resident Geologist's Office, Kenora).

L. Cousineau carried out a stripping program on his Bears Passage molybdenum property in Halkirk Township in 1985.

PROPERTY EXAMINATIONS

In 1985, the following mining and exploration properties, and mineral occurrences and prospects were examined by staff of the Kenora Resident Geologist's office as part of the regular program.

GOLD:

1. Cameron Lake, Monte Cristo, and Victor Island Prospects-Rowan Lake area
2. Combined Prospect, Phillips Township
3. Cornucopia (Cedar Island) Mine, Glass Township
4. Edwards-Fairservice Prospect, Bluffpoint Lake area
5. Electrum Lake Prospect, Ewart Township
6. Golden Star Mine and Isabella Prospect, Bad Vermilion Lake area
7. Gold Hill, Black Jack, and Golden Gate Prospects, Kirkup Township
8. Gold Washe Limited claims, Boyer Lake area
9. Kozowy Flambeau Lake Prospect, Aubrey and Van Horne Townships
10. Lynx-Canada Explorations Limited-Sparton Resources Incorporated claims, Bennett Lake area
11. Mamen Prospect, Rickaby Lake area
12. McKenzie Gray Occurrence, Bad Vermilion Lake area
13. Neda and Abraham Occurrences, Willingdon Township
14. Nor-Penn Occurrence, Clearwater Bay area
15. Ontario Gold Concessions Limited Occurrence, Shoal Lake area
16. Page Occurrence, Forgie Township
17. Pine Portage Prospect, Kirkup Township
18. Scramble Prospect, Jaffray Township
19. Sheridan claims, Atikwa Lake area
20. Sparton Resources Incorporated claims, Napanee Lake area
21. Sutherland Group Occurrence, Bennett Lake area
22. Thrasher Prospect, Lobstick Bay area
23. Treasure and Silverman Occurrences, Jaffray and Haycock Townships
24. Virginia Prospect, Atikwa Lake area

MOLYBDENUM-GOLD:

25. McNamara Lake Occurrences, McNamara Lake area

COPPER:

26. High Lake Porphyry Copper Zone, Ewart Township

DRYDEN–IGNACE ECONOMIC GEOLOGIST PROGRAM

INTRODUCTION

The Dryden-Ignace Economic Geologist Program, initiated in 1984, continued during 1985 with funding from the Ministry of Northern Development and Mines. The program encompasses an area from Eagle Lake east to Ignace, north to Vermilion Bay, and south to Lower Manitou Lake. The objective of the program is to encourage and promote mineral exploration in this general area by providing assistance and advice to prospectors and mining companies, assisting anyone who wants to start prospecting, facilitating contact between prospectors and the mining industry, monitoring local exploration activities, and establishing a data base by documenting and investigating old and new mineral occurrences.

At the beginning of the year a 10-week, 30-hour, basic prospecting course and subsequent field trip in the Dryden area was presented free of charge in Dryden. Average attendance of 60 people was maintained throughout the duration of the course. In addition, a mapping project was begun in the Flambeau Lake-Larson Bay area, immediately west of Wabigoon Lake.

During 1985, exploration was directed toward gold. A brief history of exploration for this commodity in the Dryden area was presented in the 1984 report of activities (Parker 1985).

PROPERTY EXAMINATIONS

In 1985, the following mineral occurrences, prospects, past-producing mines, and mining and exploration properties were examined.

GOLD:

1. Alto-Gardner Prospect, MacFie Township
2. Baden-Powell Mine, Buchan Bay area
3. Big Master Mine, Boyer Lake area
4. Bonanza Mine, Van Horne Township
5. Butler Lake Occurrence, Butler Lake area
6. Buffalo Occurrence, Garnet Bay area
7. Church Lake Prospect, Kawashegamuk Lake area
8. Drake Prospect, Van Horne Township
9. East Zone, Kozowy, A., Flambeau Lake Prospect, Aubrey Township, Van Horne Township
10. Eldorado Prospect, Garnet Bay area
11. Elora Mine, Boyer Lake area
12. Fornieri Bay Prospect, Buchan Bay area
13. Frenchman Island Occurrences, Harper Lake area
14. Fuchsite Zone Occurrence, Harper Lake area
15. Glatz, A., Pritchard Lake Occurrence, Van Horne Township
16. Golden Moose Occurrence, Van Horne Township
17. Golden Eagle Prospect, Garnet Bay area
18. Good Luck Prospect, Van Horne Township
19. Grace Prospect, Garnet Bay area
20. Ideal Prospect, Van Horne Township
21. Laurentian Mine, Boyer Lake area
22. League Prospect, Van Horne Township
23. Little Jumbo Prospect, Van Horne Township
24. Lone Pine Prospect, Aubrey Township
25. Lost Prospect, Van Horne Township
26. Lunch Box Bay Zone Occurrence, Boyer Lake area
27. Manhattan Occurrence, Buchan Bay area

28. McEdna Prospect, Boyer Lake area
29. New Brown Lake Occurrence, Tabor Lake area
30. New Church Lake Occurrence, Kawashegamuk Lake area
31. New East Zone, Kozowy, A., Flambeau Lake Prospect, Aubrey Township-Van Horne Township
32. New Klondike Prospect, Melgund Township
33. Niemi Occurrence, Southworth Township
34. North Twin Island Occurrence, Garnet Bay area
35. Oxford Prospect, Boyer Lake area
36. Paymaster Prospect, Boyer Lake area
37. Peninsula Zone Occurrence, Harper Lake area
38. Pidgeon-Wabigoon Lake Occurrence, Butler Lake area
39. Pioneer Island Prospect, Garnet Bay area
40. Redeemer Mine, Van Horne Township
41. Ryan Occurrence, McNamara Lake area
42. Sakoose Mine, Tabor Lake area
43. Selby Lake Prospect, Boyer Lake area
44. S.V. 372 Occurrence, Van Horne Township
45. Trafalgar Bay Zone Occurrence, Boyer Lake area
46. Vanlas Prospect, Van Horne Township
47. Viking Prospect, Garnet Bay area
48. W.W. Smith Occurrence, Buchan Bay area
49. West Zone, Kozowy, A., Flambeau Lake Prospect, Aubrey Township

INDUSTRIAL MINERALS:

50. Nelson Granite Quarry, Docker Township

MOLYBDENUM:

51. Wilkinson, D., Occurrence, Dewan Township

PROPERTY DESCRIPTIONS

The following are descriptions of a number of properties that were visited during 1985.

Butler Lake Gold Occurrence

The Butler Lake Occurrence is located on the northern shore of the western half of Butler Lake, immediately south of Wabigoon Lake, approximately 13 km southeast of Dryden. The occurrence is situated along the southern boundary of Butler Lake Provincial Park, in an area that has not recently been explored for gold. The occurrence was rediscovered by Stan and Sherridon Johnson this past summer.

Thomson (1917) briefly described the occurrence as: "two small shafts, . . . the first on a tangle of quartz stringers containing pyrite, ankerite, tourmaline, chalcopyrite and malachite, the second on a quartz vein 4 feet wide, containing the same vein material as at the first shaft. The country rock at the latter is felsite schist striking about northwest . . . ."

The author found the occurrence to consist of eight large test pits and several trenches trending in a general northwestern direction. Two of the pits appear to be shallow shafts (10 m) with fairly large rock dumps beside them. The country rocks consist of fine- to medium-grained, chloritic, carbonatized, massive mafic flows and mafic to intermediate tuffs. The metavolcanics commonly contain 1% to 5% disseminated euhedral pyrite, show a weak to intense foliation striking 320°, and are variably altered and bleached pale green-grey by silicification. The metavolcanics are intruded by single quartz-carbonate veins and stringers, stockworks of veins, and sinuous masses and clots of quartz-carbonate. The veins strike between 065° to 154°, commonly dip south and southwest, and are composed of milk white and sugary grey quartz hosting variable amounts of buff-brown to orange iron carbonate, calcite, very abundant massive black tourmaline, <1% to 2% disseminated euhedral pyrite, ≤3% irregular blebs of chalcopyrite, and ≤1% blebs of sphalerite. At one pit there is a wide breccia zone (6 m), where angular, altered, and pyritic fragments of metavolcanics are cemented by quartz-carbonate-tourmaline. The wallrocks in the trenches are intensely sheared, sericitized (fuchsite), altered by iron carbonate, and contain very abundant disseminated pyrite (up to 10%). Although the author did not observe visible gold at the occurrence, Mr. Johnson panned some good gold tails from sulphide-rich samples. The best assays from grab samples randomly taken from various quartz veins in the trenches and pits, by the author, were 100 ppb Au, 830 ppb Au, 2510 ppb Au, 4590 ppb Au, 8420 ppb Au, 0.31 ounce gold per ton and 1.6 ounces gold per ton, with a zinc assay of 2270 ppm, copper assays ranging from 415 ppm to 8760 ppm, and silver assays ranging from <2 ppm to 16 ppm (Geoscience Laboratories, Ontario Geological Survey, Toronto).

Pidgeon–Wabigoon Lake Gold Occurrence

The Pidgeon-Wabigoon Lake Gold Occurrence (also known as the I.R. 27 Occurrence) is located on claim K824976 (previously K13698) on the western shore of the extreme southeast bay of Wabigoon Lake, at the northwestern corner of Indian Reserve No. 27.

It is situated approximately 5.2 km southeast of the Butler Lake Gold Occurrence.

The occurrence was discovered by Mr. G.L. Pidgeon in 1950, who stripped, trenched, sampled, and diamond drilled three short holes totaling 53.6 m (176 feet). One hole intersected mineralized quartz between 0.3 m to 3.0 m (1 to 10 feet), assaying up to 0.19 ounce gold per ton, with a second intersection of mineralized quartz and host rock between 12.8 m and 18.3 m (42 to 60 feet) assaying up to 0.29 ounce gold per ton. The occurrence is presently held by Mr. R. Fairservice who staked the ground in 1980, and optioned to Royex Sturgex Mining Limited, who conducted horizontal loop EM and magnetometer surveys over the property in 1983. The surveys outlined two EM conductors, one of which flanks a magnetic anomaly with an arcuate form (Assessment Files, Resident Geologist's Office, Kenora).

The property consists of sheared, massive, pillowed and brecciated, fine-grained mafic flows intruded by irregular stockworks of quartz-iron carbonate stringers and veins. The metavolcanics contain 2% to 10% disseminated euhedral pyrite and are variably altered by iron carbonate, chlorite, and sericite. The wallrocks are commonly silicified,

bleached pale green to buff brown, and contain abundant pyrite and fuchsite. The metavolcanics are sheared in two directions, a strong shear striking 014° and dipping 37°E, intersected by an east-trending shear. The quartz veins crosscut the shearing at all angles, and are composed of vitreous white quartz, extremely abundant black tourmaline, pale brown and orange iron carbonate, calcite, and ≤3%, fine grained, disseminated pyrite. The pyrite is associated with iron carbonate or angular fragments of brecciated host rock within the quartz veins. The author observed small flakes and blebs of visible gold intimately associated with pyrite, in the host rock, along the edge of a quartz vein. Arsenopyrite has also been found at the occurrence (R. Fairservice, prospector, Kenora, personal communication, 1985) but none was observed by the author. Random grab samples of the altered, pyritic, mafic metavolcanics, taken by the author, assayed 300 ppb Au, 210 ppb Au, and 605 ppb Au with arsenic assays of 80 ppm, 185 ppm, and 42 ppm respectively. Grab samples taken from some of the quartz veins by the author assayed 120 ppb Au and 2050 ppb Au, with arsenic assays of 30 ppm and 290 ppm respectively. (Geoscience Laboratories, Ontario Geological Survey, Toronto).

The surrounding geology of the Wabigoon Lake-Butler Lake area, where the Butler Lake and Pidgeon Gold Occurrences are situated, consists of lenticular masses of felsic flows and agglomerates, some of which may be intrusive, intercalated with intermediate to mafic flows and agglomerates with very widespread, but selective, iron carbonate alteration. The felsic rocks are commonly fractured and altered to carbonate-sericite schist (Satterly 1943). Reconnaissance work in the area, by the author, revealed that the mafic and felsic rocks are commonly sheared, pyritic, carbonatized, and intruded by numerous quartz-carbonate-tourmaline veins.

Asarco Exploration (in 1970-71) and Sherritt Gordon Mines Limited (in 1979) conducted base metal exploration programs in the area (Assessment Files, Resident Geologist's Office, Kenora), but it has never been seriously evaluated for its gold potential.

The above observations suggest that in the Wabigoon Lake-Butler Lake area, gold mineralization is associated with quartz-carbonate-tourmaline veins and stockworks hosted by intensely sheared, pyritic, and carbonatized mafic metavolcanics. The carbonate-sericite schists described by Satterly (1943) may also be good hosts for quartz veins and sulphide mineralization associated with gold.

NEW CHURCH LAKE GOLD OCCURRENCE

The New Church Lake Gold Occurrence is located on claim K590337, immediately northeast of Church Lake, approximately 46.7 km southeast of Dryden, in the Kawashegamuk Lake area.

The occurrence is situated in an area known as the "New Klondike" which was explored for gold from the early 1900s to the late 1950s, when numerous gold occurrences were discovered north of Church Lake, including the Sakoose Mine and the Tabor Lake Prospect. During the 1960s and 1970s, several exploration companies conducted base metal exploration programs in the area without success. Gold exploration was renewed in the area in the early 1980s. At that time, Mr. A. Kozowy optioned a gold occurrence he had staked on the southeast shore of Church Lake to Teck Explorations Limited, who conducted geological mapping, VLF-EM surveys, magnetometer surveys, and diamond drilling on the property during 1983 and 1984 (Assessment Files, Resident Geologist's Office, Kenora). The occurrence consists of a single, narrow, high-grade quartz vein within a sheared, chloritic, and carbonatized magnetite-bearing gabbro. The property was returned to Mr. Kozowy when Teck subsequently dropped the option. Mr. Kozowy did more intensive prospecting in the area, this past summer, which led to the discovery of the New Church Lake Occurrence, about 400 m northwest of the old occurrence.

The general geological setting of the area consists of mafic flows and pyroclastics intercalated with intermediate and felsic flows and pyroclastics. These rocks have been intruded by numerous magnetite-bearing gabbros and small felsic intrusions which are commonly carbonatized and sericitized (Kresz *et al.* 1982). Pervasive carbonatization occurs throughout the area, as well as numerous northeasterly trending faults and northwesterly trending shear zones.

The New Church Lake Occurrence consists of a massive, medium- to coarse-grained, commonly porphyritic, dark green gabbro, containing very abundant (≤5%) disseminated, euhedral magnetite crystals (≤1 to 3 mm). A wide, vertically dipping shear zone striking 340° extends for approximately 1.6 km through the gabbro, along the northeastern shore of Church Lake, and along the western shore of Brown Lake, immediately north of Church Lake. The gabbro is moderately to intensely sheared, chloritized and carbonatized, hosting quartz stringers, veins, and variable amounts of disseminated pyrite (up to 2%). Xenoliths of gabbro in the quartz veins, and sheared gabbro adjacent to the veins is very soft, chloritic, pyritic (<1% to 2%), and intensely carbonatized with white-brown calcite and minor iron carbonate. The gabbro hosts a 1.5 to 2.1 m (5 to 7 feet) wide quartz vein composed of vitreous, white quartz, containing finely disseminated galena (1%), minor chalcopyrite (<1%) and pyrite (<1%). The author observed very fine blebs of pale yellow visible gold disseminated amongst the sulphide minerals and in massive quartz. A random grab sample of the vein taken by Mr. A. Kozowy assayed 33.68 ounces gold per ton (A. Kozowy, personal communication, 1985). Two grab samples of altered gabbro containing <1% pyrite, taken by the author, assayed 4 ppb Au and 90 ppb Au (Geoscience Laboratories, Ontario Geological Survey, Toronto).

The shear zone extends a few hundred metres northwestward along a steep, sheared cliff face where large boulders, at the bottom of the cliff, contain quartz vein material and intensely sheared gabbro altered by iron carbonate. Three old east-trending trenches at the extreme northern end of the cliff, crosscut a wide felsite dike intruding the sheared gabbro. The dike is buff-white to pink, intensely carbonatized, silicified, and pyritic (≤1%), containing abundant fuchsite and hosting numerous quartz veins which have filled fractures within the

felsite. The veins are composed of white quartz hosting minor amounts of disseminated pyrite, chalcopyrite, and galena. A grab sample of the felsite dike, taken by Mr. Kozowy assayed 0.16 ounce gold per ton (A. Kozowy, personal communication), and a grab sample from another location in the felsite, taken by the author, assayed 11 ppb Au and <2 ppm Ag (Geoscience Laboratories, Ontario Geological Survey, Toronto). The felsite dike and shear zone can be traced along the southern and western shore of Brown Lake. Two old, long, east-trending trenches on the western shore of Brown Lake crosscut sheared and altered gabbro intruded by the felsite dike which hosts thin, milk white quartz veins. Shearing remains intense, but alteration is less extensive and sulphide mineralization is not abundant. Random grab samples of the felsite and gabbro, taken by the author, assayed 5 and 7 ppb Au, respectively (Geoscience Laboratories, Ontario Geological Survey, Toronto).

Although gold mineralization is erratic along the shear zone, the area warrants more exploration, both to delineate the extent of mineralization, and to search for new gold occurrences which may be associated with other sheared gabbros hosting quartz veins and fractured felsic dikes.

Eagle Lake Gold Occurrences

There are fifteen known gold properties at Eagle Lake, situated approximately 20 km west of Dryden, that include one past producer, the Baden Powell Mine, seven prospects, and seven occurrences. Half of the properties are situated in the southwestern corner of Eagle Lake in the Eldorado Bay-South Twin Island area where intermediate and mafic metavolcanics are in contact with the Atikwa Batholith. The remainder of the properties occur within intermediate and felsic metavolcanics in the Fornieri Bay-Buchan Bay area, with the exceptions of the Lone Pine Prospect, 3.2 km east of Eagle Lake, and the Swanson Occurrence situated on the northern shore of Eagle Lake. The general characteristics of each gold property are summarized in Table 1.5. Gold exploration in the Eagle Lake area began in the early 1900s and continued until the 1940s. Many of the properties were exploited for their narrow, high grade quartz veins: for example, the Baden Powell Mine, which produced 288 ounces gold and 5 ounces silver between 1902 and 1905, had an average grade of 1.77 ounces gold per ton (Ontario Ministry of Natural Resources, Production Statistical Files, Toronto). Other properties such as the Buffalo, Eldorado, Grace, Golden Eagle, and Viking produced only minimal amounts of gold. A number of mining companies are presently conducting exploration programs in the Eagle Lake area and re-evaluating the old gold properties.

The Eagle Lake area is underlain by mafic metavolcanic flows intercalated with intermediate flows and agglomerates and felsic flows and intrusives, which are bounded by the Atikwa Batholith to the south and by clastic metasediments and derived migmatites of the English River Subprovince to the north. The Wabigoon Fault extends along the contact between the metasediments and metavolcanics. Moorhouse (1941) mapped a broad northeastward trending syncline, the axis of which extends through the metasediments immediately north of Eagle Lake. Blackburn (1981) recognized a number of northeast-trending synclinal fold axes and a northeast-trending anticlinal fold axis plunging southwestward in the Buchan Bay-Froghead Bay area. Moorhouse (1941) also recognized that the metavolcanics throughout the area were sheared or well foliated and variably carbonatized, especially the felsic and intermediate rocks which extend east from Fornieri Bay.

The gold occurrences in the Eagle Lake area can be divided into four types: 1) shear zones in granitic rocks hosting quartz veins, 2) sulphide-rich, silicified shear zones, 3) shear zones in metavolcanics hosting quartz veins, and 4) shear zones in mafic intrusive rocks hosting quartz veins. These four types are described below.

1. Shear Zones in Granitic Rocks The majority of gold properties in the Eagle Lake area, such as the Baden Powell Mine, Buffalo Occurrence, Eldorado Prospect, Golden Eagle Prospect, Grace Prospect, North Twin Island Occurrence, and Viking Prospect, located in the Eldorado Bay-South Twin Island area, consist of narrow mineralized quartz veins hosted by shear zones along the northern contact of the Atikwa Batholith, where it commonly contains xenoliths of mafic metavolcanics.

Locally, the host rock is pink to grey, medium- to coarse-grained, chloritic, biotite-hornblende granite which is commonly mylonitized and appears porphyritic, due to the presence of numerous, elliptical, blue quartz eyes, <1 mm to 3 mm in size. Shear zones are typically narrow and trend in northeast, northwest, and east-west directions. The shears host narrow quartz and quartz-iron carbonate veins and stringers which contain <1% finely disseminated euhedral pyrite, chlorite, and minor specular hematite. Wallrock alteration consists of chloritization, sericitization, variable carbonatization, pyritization, and some silicification. At the Grace Prospect, small amounts of epidote occur in the wallrocks and <1% disseminated molybdenite was found in the sheared granite at the Viking Prospect. Xenoliths of metavolcanics occur at the Grace and Viking Prospects and at the North Twin Island Occurrence. At the Grace Prospect the xenolith is 60 m long and 4.5 m wide, composed of an intensely sheared, porphyritic mafic flow intruded by narrow, pink, aplite dikes and quartz veins, which also occur along the sheared contact of the xenolith. At the Viking Prospect the xenolith is intensely sheared, 0.6 m wide and 7.5 m long, composed of a massive mafic flow intruded by quartz veins which also occur along its sheared contact. In both cases the xenoliths contain very abundant biotite retrograded to chlorite. At the North Twin Island Occurrence, narrow quartz veins and stringers containing large blebs of pyrite and chalcopyrite are situated within shear zones in the granite and along the contacts of the intermediate to mafic metavolcanic xenoliths.

Grab samples of the quartz veins and wallrock were taken at each gold property, by the author, but all samples assayed trace amounts of gold, except

TABLE 1.5 CHARACTERISTICS OF GOLD PROPERTIES IN THE EAGLE LAKE AREA

Name	Location	Host Lithology	Major (Regional) Structures	Local Structures	Mineralization Type	Associated Minerals	Wallrock Alteration	Local Intrusions
Baden-Powell Mine	South Twin Island. Pat. Claim F.M. 168	Medium to coarse grained, massive, buff grey granitic rock with large clots of carbonate and chloritized biotite.	South of a northeast-trending syncline	Narrow linear shear zone striking 150/90	A simple 0.45-1.5 m wide quartz vein hosting <1% finely disseminated pyrite.	pyrite chlorite hematite	chloritization carbonatization sericitization	Atikwa Batholith, minor feldspar porphyry dike
Buffalo Occurrence	West shore of Eagle Lake, west of Prendible Island. Formerly Pat. Claim M.H. 246	Mylonitized, massive pink, biotite-hornblende granite with numerous large blue quartz "eyes".	Northeast-trending shear zone.	Narrow, linear shear zone striking northeast	<1% finely disseminated pyrite within narrow quartz-iron carbonate veins in schistose shear zone.	Fe-carbonate pyrite chlorite	sericitization Fe-carbonatization chloritization	Atikwa Batholith
Eldorado Prospect	North shore of Eldorado Bay. Formerly Pat. Claim M.H. 338	Mylonitized, grey, biotite-hornblende granite with numerous large blue quartz "eyes".	On strike with major northeast-trending shear zone.	1.4 m wide linear shear zone striking 080°/74°N for almost 152 m.	Schistose shear zone hosting 1 m wide stockwork of quartz-iron carbonate veins and stringers containing <1% disseminated pyrite.	Fe-carbonate pyrite chlorite	sericitization Fe-carbonatization chloritization silicification	Atikwa Batholith
Fornieri Bay Prospect	Southeast shore of Fornieri Bay Claim K841884	Rhyolitic feldspar porphyry flows intruded by quartz prophyry dikes. Rocks contain <1-5% disseminated sulphides. Name	Location	Host Lithology	Major (Regional) Structures	Local Structures	Mineralization Type	Associated Minerals	Wallrock Alteration	Local Intrusions
Golden Eagle Prospect	West shore of Prendible Island. Formerly Pat. Claim McA.282	Coarse to medium grained, mylonitized grey, biotite-hornblende granite with numerous large blue quartz "eyes".	East of northeast-trending shear zone	0.6-1.2 m wide northwest-trending shear zone.	Shear zone hosts 0.3-0.6 m wide quartz vein containing xenoliths of granite and chlorite associated with $\leq$1% disseminated pyrite. Vein strikes 155°-170°/90°.	pyrtie chlorite	chloritization sericitization carbonatization pyritizatin	Atikwa Batholith
Grace Prospect	West shore of Eagle Lake, south of Pioneer Island. Formerly Pat. Claim M.H. 251	Massive, sheared, coarse-grained, grey, biotite-hornblende granite hosting a large xenolith ot porphyritic mafic flow metamorphosed to lower amphibolite grade.	Northeast-trending shear zone east of the prospect.	0.9-1.3 m side parallel shear zones striking 022°-028°/74N	Shear zones hosting thin, irregular, quartz-iron carbonate-chlorite veins and stringers with <1% disseminated pyrite.	pyrite chlorite Fe-carbonate galena sphalerite epidote	carbonatization sericitization pyritization epidotization	Aplite dikes striking 057°
Harrison, J., Occurrence	Small peninsula north of Meridian Bay Claim K79453	Massive and pillowed mafic flows	Northeast-trending syncline to the north	Two subparallel north-trending shear zones 0.9 m and 6.0 m wide, crosscut by east-trending 2.0 m wide shear zone.	Shear zones host narrow quartz-iron carbonate-tourmaline veins containing up to 5% disseminated pyrite and chalcopyrite	pyrite chalcopyrite Fe-carbonate chlorite tourmaline malachite	chloritization carbonatization sericitization silicification	None

TABLE 1.5 Continued

Name	Location	Host Lithology	Major (Regional) Structures	Local Structures	Mineralization Type	Associated Minerals	Wallrock Alteration	Local Intrusions
Lone Pine Prospect	3.2 km East of Spring Bay of Eagle Lake. Formerly Pat. Claim R.L.33	Massive, magnetite-bearing mafic vesicular flows and tuffs with thin layers of cherty interflow sediments.	Northeast-trending syncline and northwest-trending anticline.	15 m wide shear zone striking 084°/80°N.	Shear zone hosting a single 0.3-0.46 m wide quartz-iron carbonate-tourmaline vein which pinches and swells along its dip and contains 1-2% disseminated pyrite.	pyrite Fe-carbonate tourmaline chlorite	carbonatization chloritization Fe-carbonatization	None
Manhattan Occurrence	Peninsula north of Buchan Bay. Claim K677922	Seriticized and carbonatized felsic and intermediate flows and pyroclastic rocks intruded by a small magnetite-bearing, sheared, porphyritic gabbro.	South limb of northeast-trending syncline, east-trending shear zone.	Shear zone trending 073°/80°N through gabbro.	Shear zone hosting narrow quartz-iron carbonate-calcite-tourmaline veins which contain ≤1% disseminated pyrite.	pyrite Fe-carbonate calcite tourmaline chlorite chalcopyrite malachite fuchsite	Fe-carbonatization chloritization pyritization sericitization (fuchsite) silicification (bleaching)	Gabbro
Meridian Bay Occurrence	West shore of Meridian Bay. Formerly Pat. Claim S.904	Medium grained, sheared, grey granodiorite in contact with mafic metavolcanic flows.	Intense northeast-trending shear.	Northeast-trending shear zone 450 m long and 60 m wide.	Silicified shear zone hosting massive sulphide mineralization.	pyrite pyrrhotite chalcopyrite magnetite	silicification sulphidation chloritization sericitization Fe-carbonatization	Felsite dike, Atikwa Batholith
North Twin Island Occurrence	North shore of North Twin Island	Sheared, grey biotite-hornblende granite containing large xenoliths of mafic to intermediate metavolcanics.	South limb of northeast-trending syncline, east-trending shear zone.	0.3 m wide, parallel shear zones striking 080°/80°NW within granite and along granite-xenollith contacts.	Shear zones host irregular stockworks of quartz stringers and veins containing large blebs of pyrite and chalcopyrite	pyrite chalcopyrite chlorite biotite	sericitization chloritization pyritization carbonatization silicification (bleaching)	Atikwa Batholith

Name	Location	Host Lithology	Major (Regional) Structures	Local Structure	Mineralization Type	Associated Minerals	Wallrock Alteration	Local Intrusions
Pioneer Prospect	Located on Pioneer Island. Formerly Pat. Claim M.H. 248	Intermediate tuffs and flows in contact with massive and pillowed mafic flows.	South of a northeast-trending syncline; west of strong northeast shear zone.	6 m wide shear zone strikes 030°-041° along the contact between mafic and intermediate metavolcanics.	A lens of massive sulphide mineralization within a silicified shear zone.	pyrite pyrrhotite chalcopyrite	sulphidation silicification	Felsite dikes striking 047° and coarse grained feldspar porphyry dike striking 014°.
Swanson Gold Occurrence	North shore of Eagle Lake east of Table 1.6Table merly Pat. Claim McA. 230	Massive intermediate and mafic flows.	Northeast-trending syncline.	East-trending shear zone.	Shear zone hosting narrow quartz veins containing minor pyrite.	pyrite	chloritization carbonatization	None
Viking Prospect	North shore of small island west of Net Island. Pat. Claim S. 446(?)	Mylonitized, medium-grained, grey-pink biotite-hornblende granite containing numerous blue quartz eyes and and hosting a narrow, sheared xenolith of mafic metavolcanics metamorphosed to lower amphibolite grade.	Northeast-trending syncline, major east-trending shear zone.	Wide shear zone striking 068°/80°SE.	Thin, irregular, quartz-iron carbonate veins and stringers intrude sheared metavolcanics and granite. Veins host very small amount of pyrite.	Fe-carbonate specular hematite pyrite molybdenite	Fe-carbonatization chloritization sericitization	Quartz-feldspar porphyry dike striking 064°, Atikwa Batholith.
W.W. Smith Prospect	North shore of Hardrock Bay. Pat. Claims K12180 K12181 K12184 K12185	Sheared, massive and pillowed mafic flows and massive rhyolite flows intruded by felsic dikes.	South limb of major northeast-trending syncline, east-trending shear zone.	Numerous subparallel east-trending shear zones crosscut by minor north-trending shears.	Silicified, sulphide-rich shear zones in mafic rocks and quartz veins in fractures in felsic rocks.	pyrite pyrrhotite	silicification sulphidation	Northwest-trending quartz feldspar porphyry dikes

for samples taken at the Eldorado and Golden Eagle Prospects and the North Twin Island Occurrence. A sample of sheared, altered, granitic wallrock containing <1% py, taken at the Eldorado Prospect, assayed 1640 ppb Au, while a sample of the vein assayed 80 ppb Au. Two grab samples of the quartz vein at the Golden Eagle Prospect, containing <1% pyrite, assayed 45 ppb and 3500 ppb Au, while a third sample of quartz vein, containing almost no pyrite, assayed 1.10 ounce gold per ton. A grab sample of bleached, sheared granite, from the North Twin Island Occurrence, containing 3% pyrite and iron carbonate assayed 70 ppb Au, while a grab sample from a quartz vein containing 1% to 3% chalcopyrite and pyrite assayed 5450 ppb Au (Geoscience Laboratories, Ontario Geological Survey, Toronto). A 46 cm (18 inches) wide chip sample taken across a quartz vein on the property assayed 0.40 ounce gold per ton (Ontario Ministry of Natural Resources, Production Statistical Files, Toronto). Although large blebs of visible gold were observed in quartz vein material at the Viking Property, random grab samples of the vein assayed only trace amounts of gold.

The above observations suggest that post-emplacement deformation along shear zones at the edge of the Atikwa Batholith, provided sites where ore-bearing, hydrothermal fluids could circulate and deposit gold. High grade gold values are restricted to quartz veins; however, at the Eldorado Prospect, anomalous gold is present in the slightly pyritic granitic wallrock. Sheared, metavolcanic xenoliths also provided sites where the difference in competency between the granite and mafic metavolcanics caused intense shearing.

2. Sulphide–Rich Silicified Shear Zones Three gold properties, the Meridian Bay Occurrence, Pioneer Island Prospect, and the W.W. Smith Prospect, consist of northeast- and east-trending, pervasively silicified shear zones hosting gold mineralizaton associated with massive sulphides (up to 95%) composed of pyrite, pyrrhotite, chalcopyrite, and magnetite, containing variable amounts of copper and nickel. The shear zones at the Pioneer and W.W. Smith Prospects occur within mafic metavolcanics, while the Meridian Bay Occurrence is situated within hybrid granodioritic rocks of the Atikwa Batholith, along its contact with mafic metavolcanics immediately to the east. All of the zones are associated with minimal carbonate alteration, minor quartz veining, intense pervasive silicification and sulphidation, and felsite and/or quartz-feldspar porphyry dikes crosscutting or extending sub-parallel to the shear zones. Although the W.W. Smith Prospect consists predominantly of silicified shear zones, narrow quartz veins and stringers filling numerous fractures in felsic metavolcanics and intrusive rocks, have been reported to carry generally low grade gold mineralization with a few high grade values (Assessment Files, Resident Geologist's Office, Kenora).

Random grab samples of sulphide-rich material from the Pioneer Island Prospect, taken by the author, assayed 0.04 ounce gold per ton with 276 ppm Cu and 108 ppm Ni, a second sample assayed 120 ppb Au (Geoscience Laboratories, Ontario Geological Survey, Toronto). Various grab samples from the Meridian Bay Occurrence have been reported to assay between 0.20 and 0.45 ounce gold per ton, 3.0 ounces silver per ton, 0.9 to 4.22% copper, and 0.5 to 1.0% nickel (Ontario Ministry of Natural Resources, Statistical Files). A grab sample of sulphide-rich material, taken by the author, assayed <0.01 ounce gold per ton, 965 ppm copper, and 82 ppm nickel.

The W.W. Smith Prospect in Hardrock Bay, evaluated by Birch Bay Gold Mines from 1936 to 1938, Magdalena Red Lake Mines Limited in 1948, and Tasu Resources from 1982 to 1984, to date contains the best reported gold mineralization of the three deposits. Magdalena Red Lake Mines Limited reported that the best concentrations of gold were found in sulphide replacement zones in mafic metavolcanic flows. Three channel samples from two separate shear zones, taken by the company, assayed 0.145 ounce gold per ton over 18.3 m (60 feet), 0.146 ounce gold per ton over 7.6 m (75 feet), and 0.146 ounce gold per ton over 12.2 m (40 feet). Nine holes drilled by Birch Bay Gold Mines in 1938 intersected narrow zones of generally low grade gold mineralization, although one hole targeted on a silicified, sulphide-rich zone on a small island, located in Hardrock Bay, intersected 12.2 m (40 feet) of 0.10 ounce gold per ton. Three holes drilled on the property by Tasu Resources in 1984, intersected narrow zones of low grade gold mineralization ranging from 0.025 to 0.20 ounce gold per ton (Assessment Files, Resident Geologist's Office, Kenora). Two random grab samples of silicified mafic metavolcanics containing 3% sulphide mineralization, taken by the author from the trenches at the W.W. Smith Prospect, assayed 60 ppb gold and 1.28 ounces gold per ton, while a sample containing 1% sulphide mineralization assayed 0.38 ounce gold per ton. A grab sample, taken by the author, from a quartz-feldspar porphyry dike crosscutting the property, and containing no visible sulphide mineralization, assayed 85 ppb Au, while a grab sample containing >10% pyrrhotite, also taken by the author from the sulphide zone on the small island in Hardrock Bay, assayed 0.08 ounce gold per ton, 2150 ppm copper, and 30 ppm nickel (Geoscience Laboratories, Ontario Geological Survey, Toronto).

The above observations suggest that post-deformation, sulphide-rich, gold-bearing, hydrothermal solutions circulated through shear zones within metavolcanics and dioritic rocks and, due to the ductile nature of the shear zones, pervasively silicified, sulphidized, and replaced the host rock, rather than forming discrete quartz veins. Moorhouse (1941) suggested that the Meridian Bay Occurrence may be "a replacement of an inclusion in hybrid diorite."

3. Shear Zones in Metavolcanics The Lone Pine Prospect, Harrison Occurrence, and Swanson Occurrence all consist of relatively narrow, linear shear zones in massive and pillowed mafic flows which host quartz-iron carbonate-tourmaline veins and stringers containing abundant (1% to 5%) disseminated pyrite and chalcopyrite (Harrison Occurrence). Wallrocks are typically sheared, chloritized, sericitized, and carbonatized by either iron carbonate or calcium carbonate, and contain variable amounts of

pyrite. At the Lone Pine Prospect the mafic metavolcanics, a few metres on either side of the mineralized vein, contain abundant (5%) disseminated crystals of magnetite up to 4 mm in size.

The Fornieri Bay Prospect is an exception to the other deposits, since it occurs in felsic metavolcanics composed of massive, rhyolitic, feldspar porphyry flows intruded by quartz porphyry dikes. East-trending shear and fracture zones host narrow, white and blue-grey quartz veins and stringers containing <1% disseminated sulphide minerals consisting of pyrite, pyrrhotite, and minor chalcopyrite. Moorhouse (1941) observed visible gold and a silvery columnar mineral he identified as bismuthinite. Wallrocks are silicified, chloritized, and weakly carbonatized, containing <1% to 5% disseminated pyrite and pyrrhotite. Erie Canadian Mines Limited (1939) reported that gold mineralization occurred in strong east-west shear zones within the rhyolite, and in the noses of small drag folds in the veins (Moorhouse 1941). It is unlikely that the quartz veins were drag folded, owing to the brittle nature of the extremely siliceous host rocks. A grab sample, taken by the author, from a pyritic (<1%) quartz vein in one of the many trenches on the property assayed 45 ppb Au, while a grab sample from a pyritic (1%) feldspar porphyry assayed 50 ppb Au (Geoscience Laboratories, Ontario Geological Survey, Toronto).

Raleigh Resources Limited have drilled 18 holes totaling 1699 m (5574 feet) from 1982 to 1985, in the vicinity of the Fornieri Bay Prospect. Sulphide-rich samples of fractured rhyolite, containing narrow quartz stringers, taken from a hole drilled in the vicinity of the old trenches in 1982, assayed 0.057 ounce gold per ton over 3 m (10 feet), and 0.374 ounce silver per ton, and 0.65% Cu over 1.5 m (5 feet). Holes drilled south and west of the trenched area in 1983, intersected relatively narrow diorite and gabbro dikes intruding rhyolitic flows and felsic tuffs hosting wide intervals of abundant (4% to 5%) pyrite, pyrrhotite, and chalcopyrite in quartz-carbonate veinlets, along fractures, and disseminated throughout moderately sheared rocks. These wide sulphide-rich intersections were found to host anomalous gold mineralization assaying 0.013 ounce gold per ton over 30 m (98 feet), and 0.025 ounce gold per ton over 40.5 m (132.8 feet), including a smaller intersection of 0.036 ounce gold per ton over 21.3 m (70 feet). In 1985, further drilling intersected more sections of anomalous gold, with one intersection assaying 0.24 ounce gold per ton over 1.1 m (3.5 feet) (Assessment Files, Resident Geologist's Office, Kenora).

The author observed small flakes of visible gold in quartz vein material from the Lone Pine Prospect and collected two grab samples of pyritic (<1%) quartz vein material which assayed 55 and 140 ppb Au, while a grab sample, taken by the author, of the altered, pyritic (1%), wallrock assayed 100 ppb Au. Grab samples, taken by the author, from other quartz-carbonate veins in the vicinity of the Lone Pine Prospect assayed only trace amounts of gold (Geoscience Laboratories, Ontario Geological Survey, Toronto). Four grab samples taken by the author, from the pyrite- and chalcopyrite-bearing quartz veins at the Harrison Occurrence, assayed 0.02 ounce gold per ton with 4880 ppm Cu, 0.22 ounce gold per ton with 0.46 ounce silver per ton and 2.22% Cu, 0.01 ounce gold per ton with 5760 ppm Cu, and <0.01 ounce gold per ton with 1640 ppm Cu (Geoscience Laboratories, Ontario Geological Survey, Toronto). Most of the samples contained between 5% and 10% pyrite, chalcopyrite, and malachite. Although the author did not visit the Swanson Gold Occurrence, Mr. A. Glatz, a prospector who recently staked the occurrence, found abundant visible gold in quartz vein material on the property (A. Glatz, personal communication, 1985).

4. Shear Zones in Mafic Intrusive Rocks The Manhattan Occurrence is the only gold deposit of this type. It consists of a sheared, chloritic, carbonatized, gabbro, intruding intermediate to felsic flows and pyroclastics. The gabbro is medium grained and porphyritic, containing large (≤1 cm), rounded, green-white feldspar phenocrysts, round blue quartz eyes (≤5 mm in size), variable amounts of biotite, and up to 5% disseminated magnetite crystals. An east-trending shear zone extends through the gabbro and hosts quartz-iron carbonate-calcite-tourmaline veins and stringers containing ≤1% disseminated pyrite. The wallrocks are intensely sheared, variably silicified, bleached pale green, and contain abundant iron carbonate, fuchsite, and disseminated pyrite (≤5%) with minor blebs of chalcopyrite and malachite. A grab sample, taken by the author, of altered, sheared gabbro, containing approximately 2% pyrite and 1% chalcopyrite, assayed 115 ppb Au and 805 ppm Cu, while a sample of altered gabbro containing no sulphide mineralization assayed 7 ppb Au and 113 ppm Cu. A grab sample, taken by the author, from quartz vein material containing 2% pyrite, assayed 720 ppb Au and 198 ppm Cu (Geoscience Laboratories, Ontario Geological Survey, Toronto).

Summary and Conclusions The above observations have shown that all the gold deposits in the Eagle Lake area are associated with linear shear and/or fracture zones commonly trending east or northeast within granitic rocks of the Atikwa Batholith, adjacent metavolcanics, and mafic intrusive rocks. Moorhouse (1941) suggested that the widespread shearing and the variable trend of shearing, which changes abruptly throughout the area, demonstrates the "consistent parallelism of the strike of bedding and schistosity to the general boundary of the main intrusive masses" (Atikwa Batholith). Zircon U-Pb geochronology studies (Davis *et al.* 1982) have also shown that the batholithic rocks dated at approximately 2731.8 Ma are slightly younger than adjacent metavolcanics dated at approximately 2742.8 Ma, suggesting that the metavolcanics at Eagle Lake may be extrusive equivalents of the Atikwa Batholith. All of these observations suggest that shearing and fracturing in the area was developed during and after the emplacement of the Atikwa Batholith, and that the timing of the gold deposition was late.

The different types of gold deposits in the Eagle Lake area all share their own specific characteristics, which implies that multiple hydrothermal systems occurred in the area at different times. The gold-bearing quartz veins hosted by sheared granitic rocks commonly contain <1% disseminated pyrite, relatively

minor amounts of iron carbonate, and alteration characterized by sericitization, chloritization, carbonatization, and silicification restricted to the immediate sheared wallrocks. The silicified, sulphide-rich shear zones commonly contain very abundant sulphide mineralization (>50%), which has partially replaced the host rocks and contains anomalous copper and nickel. Shear zones hosting quartz veins in mafic metavolcanics and mafic intrusive rocks, are characterized by carbonatization, chloritization, and sericitization in the wallrocks, and quartz-iron carbonate-tourmaline veins, commonly containing 1% to 5% pyrite, with variable amounts of chalcopyrite. Shear and fracture zones hosting quartz veins in felsic metavolcanics, are characterized by the presence of a variety of disseminated sulphide minerals within silicified and weakly carbonatized host rocks.

Exploration Guidelines There are numerous gold deposits in the Eagle Lake area, but the majority of them consist of single quartz veins and/or quartz stringers within narrow shear zones which have limited economic gold potential, due to their narrow widths and relatively short strike lengths. However, the presence of anomalous gold within sheared, altered, pyritic, granitic rock at the Eldorado Prospect and North Twin Island Occurrence suggests that the Atikwa Batholith may have the potential to host high-tonnage, low-grade gold deposits. A similar geological situation occurs in the Bluffpoint Lake area, where an altered trondhjemitic phase of the Lawrence Lake Batholith hosts wide alteration zones containing anomalous gold, and is currently under investigation by Corporation Falconbridge Copper (*see* "Straw Lake Area"). Blackburn (1982) briefly described the geology of this area and suggested that the Eagle Lake area warrants investigation for similar deposits.

Other deposits which are favourable targets for gold exploration are the sulphide-rich silicified shear zones and sheared and fractured zones within felsic metavolcanics. These types are known to host anomalous gold mineralization over considerable widths and strike lengths and are found at the Fornieri Bay Prospect (shear and fracture zones in felsic metavolcanics) and the W.W. Smith Prospect (sulphide-rich silicified shear zones in mafic metavolcanics). The greater widths can be attributed to the brittle nature of the felsic rocks, which causes them to fracture and shear when deformed, providing abundant closely spaced open fissures for the deposition of gold. The ductile nature of mafic metavolcanics has caused them to shear along discrete planes, which form fewer and more limited open fissures; except in the case of the pervasively silicified sulphide-rich zones, where hydrothermal solutions have invaded the fabric of the sheared rocks and replaced it with sulphide mineralization.

The extensive felsic metavolcanics which extend east from Fornieri Bay to Buchan Bay, consist predominantly of massive, sericitic, carbonatized quartz and feldspar porphyries and carbonate schists, which are known to be good host rocks for gold mineralization. Areas of mafic metavolcanics should also be explored for sulphide-rich silicified shear zones similar to the zones at the W.W. Smith Prospect.

FLAMBEAU LAKE–LARSON BAY MAPPING PROJECT

The Flambeau Lake-Larson Bay map area in Van Horne and Aubrey Townships lies approximately between Latitudes 49°43′ and 49°44′ and Longitudes 92°51′ and 92°57′ in the District of Kenora, and covers a 23.5 km^2 area which is 2.88 km wide by 8.16 km long. Flambeau Lake in the west and Larson Bay of Wabigoon Lake in the east are about 6.4 km south of Dryden. The area is accessible by Highway 502, Ojibway Drive, the Wabigoon Lake Road and numerous access roads and trails. J. Parker, assisted by R. Schienbein, began a geologic survey in 1985, using a base map prepared at a scale of 1:4800 (1 inch to 400 feet) by enlargement from Forestry Resources Inventory Maps, with corrections from vertical air photographs enlarged to the same scale. Compilation of geological mapping done by T.S. Joliffe for Van Horne Gold Exploration Incorporated, and by F.W. Gittings for Voyager Explorations Limited (Assessment Files, Resident Geologist's Office, Kenora) was included in the preparation of Open File Map 33. The cooperation of Kidd Creek Mines Limited is also greatly appreciated.

The Flambeau Lake-Larson Bay area was the scene of intensive gold exploration between 1897 to 1917, 1920 to 1925, and again from 1938 to 1940. There are 13 known gold properties in the area, that includes two past producers, the Redeemer and Bonanza Mines, 9 prospects and 2 occurrences. The majority of the properties, including the Redeemer and Bonanza Mines, are situated in the eastern part of the map area, west of Larson Bay, while the remainder are located immediately north, east, and west of Flambeau Lake.

Gold exploration began at the Little Jumbo Prospect, north of Guy Lake, in 1897, followed by the development of the Redeemer Mine, which produced approximately 351 ounces of gold between 1904 and 1906. The Redeemer was re-evaluated between 1910 and 1911, and produced another 8 ounces of gold in 1918. During this time other properties in the area were being exploited, but none of them produced any appreciable amounts of gold. Between 1920 and 1923 the Bonanza Mine produced 246 ounces of gold and 83 ounces of silver from 1206 tons milled at an average grade of 0.20 ounce gold per ton (Ontario Ministry of Natural Resources, Production Statistical Files, Toronto). Gold exploration was renewed in the 1980s by Voyager Explorations Limited at Flambeau Lake, and by Van Horne Gold Exploration Incorporated who re-evaluated numerous old gold properties near Larson Bay (Assessment Files, Resident Geologist's Office, Kenora). Kidd Creek Mines Limited has recently optioned a promising gold prospect on the north shore of Flambeau Lake, where Voyager Explorations Limited did work during 1983 and 1984.

General Geology

The map area is situated within the Lower Wabigoon Volcanic Group, a mixed sequence of mafic to felsic metavolcanics, that overlies the Eagle Lake Volcanic Group, a thick sequence of massive and pillowed mafic flows, and underlies the Upper Wabigoon Volcanic Group, a pillowed mafic flow sequence occurring at the top of the volcanic succession. All three

groups are characterized by predominantly tholeiitic rocks with distinct iron-enrichment trends (Trowell *et al.* 1980). The metavolcanics are bounded by the Atikwa Batholith to the south and by clastic metasediments and derived migmatites of the English River Subprovince to the north.

Zircon U-Pb geochronology (Davis *et al.* 1982) has shown that the Lower Wabigoon Volcanics were deposited over a period of approximately 8 million years, and are about the same age or slightly older (minimum age of about 2734.8 Ma), than rocks of the Atikwa Batholith (minimum age of about 2731.8 Ma) which suggests that the metavolcanics of the Lower Wabigoon Volcanic Group are the extrusive equivalents of the Atikwa Batholith.

About 4.8 km north of the map area, the Wabigoon Fault extends in an east-west direction along the contact between the metasediments in the north and metavolcanics to the south. The metavolcanics are folded about a number of tight east-trending folds close to the Wabigoon Fault (Blackburn *in* Trowell *et al.* 1977). Blackburn (1981) recognized an east-trending lineament which extends through Larson Bay of Wabigoon Lake. Satterly (1943) noted that the Wabigoon Volcanics which extend southwards from Wabigoon Lake to the Atikwa Batholith, were all north- to northeast-facing, based on 81 top determinations from pillow lavas.

The map area is underlain by lower greenschist facies mafic to felsic metavolcanics consisting of massive and brecciated flows intercalated with pyroclastic flows. The metavolcanics are intruded by intermediate and mafic dikes, felsic dikes and gabbro, diorite, and quartz-diorite dikes and stocks.

The metavolcanics in the Flambeau Lake-Larson Bay area can be subdivided into the following four map groups: mafic, intermediate to mafic, intermediate to felsic, and felsic. Factors such as colour of the fresh surface, colour of the weathered surface, hardness, visible quartz content, and mafic mineral content were used to assign them to their respective categories.

Massive, brecciated, and pillowed mafic and intermediate to mafic flows occur throughout the area. They are typically fine-grained, light to dark green-grey, extremely chloritic, carbonatized, amygdaloidal, pyritic, variably magnetic, and contain epidote pods. They consist dominantly of autoclastic flow breccias composed of angular pillow fragments, scoriaceous amygdaloidal material and devitrified hyaloclastite intimately intermixed with intermediate to mafic pyroclastics. Pillowed flows are common south of Flambeau Lake and south and north of the Bonanza Mine near Larson Bay. Pillows are typically large (up to 1.8 m long and 1.2 m wide), with thick (<2.5 to 7.6 cm) selvages and large (≤3 cm) abundant amygdules. Interpillow material is common and consists of ashy intermediate to felsic material which drapes the pillows and occurs between them. Massive mafic flows are commonly fine- to medium-grained and amygdaloidal, however, coarse-grained magnetite-bearing flows were found west of Flambeau Lake, immediately south of Ojibway Drive. Massive intermediate to mafic, fine- to coarse-grained, light to dark green-grey flows are commonly found south of the Bonanza Mine and along the northern shore of Guy Lake. Most of them are dioritic to gabbroic with ≤35% to 50% mafic minerals, with quartz and magnetite as common accessory minerals. T.S. Joliffe of Van Horne Gold Exploration Incorporated interpreted these rocks to be major sills (Assessment Files, Resident Geologist's Office, Kenora); however, their conformable nature and the lack of observed intrusive contacts have led the author to interpret them to be massive flows.

All of the felsic metavolcanic flow rocks are located in the vicinity of Flambeau Lake in the western part of the map area. These consist dominantly of felsic autobreccias intercalated with felsic pyroclastics, where the distinction between autoclastic and pyroclastic phases can be subtle. An extensive unit of rhyolitic brecciated flows and pyroclastics is located along the eastern shore of Flambeau Lake and extends eastward to Bob Lake. These rocks are extremely fine-grained, weather buff white-grey to pink, and are typically sericitic and weakly to moderately carbonatized, containing variable amounts of disseminated magnetite and pyrite. Less extensive units of brecciated felsic flows are located immediately south of Pritchard Lake and immediately north of Flambeau Lake, where they are located adjacent to a small quartz-diorite stock, and where they seem to merge into the stock.

Most of the felsic flows grade into thick units of intermediate to felsic brecciated and massive flows and pyroclastics, which are situated in a broad area north of Bob Lake and extend eastward to Larson Bay. These rocks are very similar to the felsic flows, but are darker grey and contain more abundant mafic minerals and disseminated pyrite. The felsic and intermediate to felsic flows commonly host narrow pyritic quartz-iron carbonate veins which have filled tension fractures and shear zones.

Pyroclastic metavolcanics are abundant throughout the area and consist of heterolithic, poorly sorted, pyroclastic flows, which include debris flows and tuff-breccias, with a common chaotic appearance.

Of the four pyroclastic map groups, intermediate to mafic and mafic pyroclastics are the most abundant in the area, and are dark green-grey, chloritic, carbonatized, and pyritic, consisting of rounded to angular, lapilli-size, intermediate fragments, with less abundant mafic and felsic fragments within a fine-grained to gritty, intermediate to mafic matrix. The intermediate and mafic fragments may be porphyritic, vesicular, or amygdaloidal and are commonly accessory. Abundant angular, intermediate to mafic blocks, usually 6.4 cm to 28 cm in size, were observed in many outcrops in the Larson Bay area and south of Flambeau Lake. The proportion of fragments to matrix varies considerably (30% to 90% fragments), and the pyroclastics may or may not be fragment supported. The pyroclastic flows south of Flambeau Lake are commonly intimately intermixed with mafic brecciated flows and are very thickly bedded with ash layers containing small (≤1 cm) felsic to intermediate fragments.

Intermediate to felsic pyroclastics share much the same characteristics as the intermediate to mafic rocks, except that the matrix is usually intermediate

and dark grey, containing variable amounts of biotite and chlorite. These pyroclastics are commonly fragment supported where the fragments are typically lapilli-size and composed of cherty, white, angular, felsic fragments, sub-rounded intermediate fragments, and sub-rounded to angular mafic fragments. Large intermediate to mafic blocks are common but not abundant.

The felsic pyroclastics are situated in the immediate Flambeau Lake area and consist of rounded to sub-rounded, cherty and siliceous lapilli-size fragments, which are fragment supported (>80% fragments) in a slightly chloritic and sericitic felsic matrix. These pryoclastics are commonly intercalated with autobrecciated flows east of Flambeau Lake.

A thin minor unit of intermediate to felsic crystal tuff is situated in a roadcut on Highway 502, south of Flambeau Lake, at the south boundary of the map area. It consists of irregular shards and crystals (≤2 mm in size) of white feldspar phenocrysts in a fine-grained, dark grey-green, siliceous matrix.

Thin units of reworked and bedded, intermediate to felsic tuffs randomly occur throughout the area and can be observed several metres east and south of the Redeemer Mine, in scattered outcrops in the northwestern corner of the map area, southwest of Flambeau Lake and along the south shore of Larson Bay. They consist of thinly bedded and evenly laminated, fine-grained, silty and sandy, tuffaceous material, which may be crossbedded and is typically interbedded with gritty and pebbly material. A scour-and-fill channel containing coarse pebbly material occurs in evenly laminated sandy layers and can be observed in an outcrop east of the Redeemer Mine shaft.

Numerous, fine-grained, grey to dark grey-green, mafic to intermediate dikes occur throughout the area, with a dominant easterly trend. They are very abundant around Larson Bay (Bruce 1925) and in the Flambeau Lake area, where they are commonly vesicular, amygdaloidal, and porphyritic with "flow-banding" occurring along the edges of the dikes, parallel to their contacts. Abundant mafic dikes intrude a gabbro situated southwest of Flambeau Lake and appear to have been plastically deformed when the gabbro and dikes were in a semi-molten state.

Gabbro and diorite intrusions are common in the immediate Flambeau Lake area, where an extensive and previously unmapped gabbro extends from the north shore of Flambeau Lake to the southwestern corner of the map area. It intrudes a small quartz-diorite stock on the north shore of Flambeau Lake and is flanked to the north by relatively small, elliptical, diorite intrusions.

The gabbro is typically massive, fine- to coarse-grained and dark green, containing variable amounts of accessory quartz, magnetite, and biotite. The gabbro also contains abundant xenoliths of intermediate to felsic pyroclastics along its contact boundary and a few large epidote pods. In some outcrops the gabbro appears to be dioritic, which suggests the presence of numerous intermediate phases. On the northern shore of Flambeau Lake the gabbro is carbonatized, chloritized, silicified, and pyritic, making identification difficult.

The dioritic intrusions in the area are massive, pale grey, and fine- to medium-grained containing abundant accessory magnetite. In comparison to the gabbro they contain less mafic minerals and much more abundant feldspar and quartz. Most of the diorites near Flambeau Lake are intensely silicified, carbonatized, sericitized, chloritized, and pyritic, which makes identification of original mineralogy virtually impossible. Unaltered small gabbro and diorite intrusions were also mapped east of Flambeau Lake and at the Ideal Prospect immediately west of Twingrass Lakes.

The majority of felsic intrusive rocks consist of fine-grained, buff white-grey and pink, quartz-feldspar porphyry and felspar porphyry dikes which occur throughout the area. The dikes may be 6 cm to 30 m wide and consist of small (≤2 mm), white feldspar and quartz phenocrysts in a siliceous, fine-grained matrix which may or may not contain up to 5% mafic minerals (biotite, hornblende), disseminated pyrite and magnetite. The rocks are commonly carbonatized and sericitic where sheared or fractured. The dikes strike in a general northwestern direction throughout the area, however, they are more east-trending in the Larson Bay area. Felsite dikes are also common and are of the same composition as the porphyries except that they are extremely fine-grained, phenocrysts are absent and disseminated magnetite is more abundant.

A second type of felsic intrusive rock occurs as a small quartz-diorite stock located on the north shore of Flambeau Lake. It is the host to gold-bearing quartz veins occurring in tension fractures. It is typically fine- to medium-grained, consisting of approximately 60% to 70% quartz, 25% to 40% feldspar, and up to 3% mafic minerals retrograded to chlorite. Original mineralogy is obliterated by intense alteration which occurs throughout the stock. A "clotty" phase of quartz-diorite occurs along its northern contact: dark green and pale grey clots (≤1 cm in size), consisting of chlorite, sericite and carbonate, and sericite-carbonate respectively, occur in a fine-grained siliceous ground mass. The quartz-diorite contains abundant fine-grained disseminated magnetite (up to 5%) and pyrite.

A diabase dike of undetermined Proterozoic or Archean age trends in a northwestern direction across the western part of the map area, north of Flambeau Lake. The dike varies in width from 30 to 90 m and is dark grey-green, fine- to coarse-grained and massive, with typical rusty weathering.

Structural Geology

In the Larson Bay area, bedding orientations and rock contacts in the metavolcanics are generally east-trending and dip steeply to the north, with pillows and sedimentary structures consistently facing north. In the western part of the area around Flambeau Lake, bedding orientations and rock contacts change to a general northeastern trend, with pillows facing northwest in the southwestern corner of the map area. This change of orientation suggests a broad, arcuate bend in the metavolcanics from east to west. Folia-

tion is generally uniformly east-trending, and steeply dipping to vertical throughout the map area, with lineations in the vicinity of Flambeau Lake plunging steeply to the west or northwest.

Numerous sub-parallel to parallel linear shear zones, striking between 075° and 100°, and dipping steeply to the north or vertical, occur within mafic and intermediate metavolcanic and intrusive rocks throughout the area. These zones can vary in width from <1 m to 90 m with considerable strike lengths, and are commonly associated with quartz-carbonate veins, felsic dikes, carbonate alteration, and gold mineralization. The overall east-west trend of the shear zones suggests that they were developed parallel to the Wabigoon Fault located north of the map area. Mafic dikes in the map area are dominantly east-trending and may be controlled by east-trending structures.

Numerous *en echelon* tension fractures in felsic intrusive rocks and felsic metavolcanics are common in the western part of the area in the vicinity of Flambeau Lake. The fractures commonly trend between 120° and 150°, dip steeply to the north, and are associated with quartz-carbonate veins, carbonate alteration and gold mineralization. The dominant northwesterly trend of felsic dikes, as well as the overall northwesterly trend of the diabase dike, suggests that these fractures controlled the emplacement of late intrusive rocks. The fractures are intrepreted to be related to dextral movement on the Wabigoon Fault, during simple shear deformation, where tension fractures are developed perpendicular to the maximum elongation (Ramsay 1967).

A feature which occurs only locally, west of Flambeau Lake, is a narrow northeast-trending mylonite zone within massive intermediate to felsic flows and mafic amygdaloidal flows. The mafic flows are very intensely sheared, while the felsic flows display a mylonitic texture where narrow (<1 cm) anastomosing shear planes, consisting of sericite, envelop lenses of relatively undeformed rock. A crenulation cleavage can also be observed within the mylonite zone. The local significance of the zone is problematical, however, it may represent a structural feature which has developed perpendicular to the maximum shortening direction during dextral movement on the Wabigoon Fault.

Alteration

Weak to moderate iron-carbonate alteration is commonly present in the metavolcanics and felsic intrusive rocks throughout the area; however, the most intense alteration is confined to numerous shear and fracture zones. Moderate to intense and extensive iron carbonate alteration is associated with gold and sulphide mineralization immediately north of Flambeau Lake, in a broad zone extending east from Pritchard Lake, and in the rocks northeast of the Bonanza and Redeemer Mines. The felsic metavolcanics east of Flambeau Lake are weakly to moderately carbonatized and are commonly sericitic. Other types of alteration such as sericitization, chloritization, silicification, and pyritization are restricted to the wallrocks of shear zones hosting quartz veins which are commonly gold-bearing.

Gold Occurrences

The general characteristics of each gold property in the Flambeau Lake-Larson Bay map area are summarized in Table 1.6. The gold deposits can be divided into two types: 1) shear zones in metavolcanics and felsic intrusive rocks hosting quartz veins; and 2) tension fractures in metavolcanics and felsic intrusive rocks hosting quartz veins. These two types are described below.

1. Shear Zones in Metavolcanics and Felsic Intrusive Rocks The majority of gold properties in the map area, except for the East, New East, and West Zones on the Flambeau Lake Prospect, consist of mineralized quartz-carbonate veins, stringers, and stockworks hosted by east-trending linear shear zones of variable widths within mafic to felsic metavolcanics and felsic intrusive rocks. Veins typically consist of white quartz, variable amounts of orange iron carbonate, buff-brown to yellow calcite, abundant black tourmaline, and minor (≤1%) finely disseminated pyrite with accessory sulphide minerals such as chalcopyrite, galena, and sphalerite. Weak to moderate wallrock alteration usually consists of carbonatization and chloritization, which may be accompanied by sericitization, silicification (bleaching), pyritization, and tourmalinitization. Almost all of the gold properties in the Larson Bay area, such as the Bonanza and Redeemer Mines, have weak to moderate wallrock alteration strictly confined to the sheared host.

Quartz-feldspar porphyry and felsite dikes are associated with almost all of the gold properties in the map area. Quartz-carbonate veins and stringers typically occur within the dikes or along their sheared contacts. The dikes are variably carbonatized, sericitic, and silicified, containing <1% to 2% disseminated pyrite, while the felsic dikes at the Vanlas and League Prospects contain variable amounts of disseminated magnetite as well as pyrite. Felsic dikes are generally east-trending in the Larson Bay area, and northwest-trending felsic dikes occur at the Flambeau Lake Prospect and in the surrounding Flambeau Lake area, however, none of them are known to host gold-bearing quartz veins.

The Ideal Prospect is an exception to the gold properties described above, since it consists of a small dioritic stock intruded by a wide quartz-feldspar porphyry dike. A wide, intense, east-trending shear zone extends through the diorite and porphyry dike, with quartz veins occurring in the diorite and along the diorite-porphyry contacts, however, the most abundant quartz veins occur within the dike, where alteration and pyritization appears to be the most intense.

The majority of gold occurrences in the Larson Bay area were sampled by the author and by Van Horne Gold Exploration Incorporated, assay results from the sampling are listed in Table 1.7. Most of the assay results were erratic, however, almost all of the quartz veins that were sampled carried gold.

The best consistent assay results were obtained from samples, taken by the author, from trenches and dumps on the Vanlas Prospect. The Glatz Occurrence, the two Vanlas shafts, and numerous trenches located between them, occur within a broad zone of

TABLE 1.6 CHARACTERISTICS OF GOLD PROPERTIES IN THE FLAMBEAU LAKE - LARSON BAY MAP AREA

Name	Location	Host Lithology	Major (Regional) Structures	Local Structures	Mineralization Type	Associated Minerals	Wallrock Alteration	Local Intrusions
Bonanza Mine	400 m east of Twingrass Lakes Conc.1 Lot 7 Van Horne Township Claim K533304	Intermediate to mafic pyroclastic flows and flow breccias.	East-trending lineament and Wabigoon Fault north of the property.	Narrow shear zones trending 082°/90°.	Shear zones host narrow, lenticular quartz-carbonate-tourmaline veins containing ≤1% pyrite.	pyrite tourmaline calcite sphalertie galena hematite	chloritization carbonatization	Northwest-trending quartz-feldspar porphyry dikes and east-trending mafic dikes.
Drake Prospect	430 m west of Twingrass Lakes. Conc. 1 Lot 9 Van Horne Township Patented Property	Intermediate to mafic pyroclastic flows and flow breccias.	East-trending lineament and Wabigoon Fault, north of the property.	Very narrow linear fracture and shear zone trending 090°-095° for more than 245 m.	Shear zone hosts very narrow (≤0.3 m) linear quartz-iron carbonate-tourmaline vein containing 1% pyrite.	pyrite chlorite tourmaline calcite Fe-carbonate	silicification chloritization sericitization pyritization carbonatization	None
East Zone, Flambeau Lake Prospect	North shore of Flambeau Lake Conc.1 Lot 1 Aubrey Township Conc 1 Lot 12 Van Horne Township Pat. Claims A.L. 83 and A.L. 90	Magnetite-bearing, massive quartz diorite.	East-trending Wabigoon Fault north of the property.	Local tension fractures trending 130°-140°, crosscut by narrow east-trending shears.	Abundant tension fractures host numerous, subparallel quartz veins containing ≤1% pyrite.	pyrite magnetite tourmaline chalcopyrite sphalerite galena	silicification bleaching pyritization carbonatization sericitization Fe-carbonatization chloritization	gabbro, northwest-trending felsite and quartz-feldspar porphyry dikes crosscutting east-trending mafic and intermediate dikes.
Glatz, A., Pritchard Lake Occurrence	Immediately east of Pritchard Lake, Conc. 1 Lot 11 Van Horne Township Claim K672567	Immediate to mafic pyroclastic flows and tuffs and flow breccias.	On strike with wide east-trending shear zone. Property is south of Wabigoon Fault.	Several narrow, subparallel shear zones, striking 075°/90°.	Shear zones host narrow quartz-tourmaline veins containing 1% pyrite.	pyrite tourmaline chlorite	chloritization sericitization carbonatization	Northwest-trending feldspar porphyry dikes.

**Assessment Files, Kenora Resident Geologist Office

moderate to intense carbonate alteration associated with east-trending shearing and fracturing which extends eastward from Pritchard Lake within intermediate to mafic pyroclastics. Numerous pyritic quartz veins occur throughout the zone, as well as east-trending felsic dikes commonly containing variable amounts of disseminated pyrite and magnetite, and hosting quartz veins. A grab sample of pyritic (<1%) quartz vein material, taken by the author, from a trench at the Glatz Occurrence, located 140 m east of Pritchard Lake, assayed 3530 ppb Au. Grab samples from quartz veins in trenches west of the Vanlas No. 1 shaft assayed 1300 and 3150 ppb Au. Grab samples of pyritic quartz vein material from the dump at the Vanlas No. 1 shaft assayed 1110 and 9700 ppb Au, while a grab sample of carbonatized, magnetic, pyritic (<1%) felsite, taken from the dump assayed 450 ppb Au. A grab sample from quartz vein material on the dump of the Vanlas No. 2 shaft assayed 3730 ppb Au, while a grab sample of magnetic, pyritic (2%) felsite and quartz vein material taken from the dump, assayed 1140 ppb Au (Geoscience Laboratories, Ontario Geological Survey, Toronto). Sampling done by T.S. Joliffe of Van Horne Gold Exploration Incorporated, also indicates that gold mineralization occurs throughout this broad zone of carbonate alteration, fracturing, and shearing (Assessment Files, Resident Geologist's Office, Kenora).

2. Tension Fractures in Metavolcanics and Felsic Intrusive Rocks Gold-bearing quartz veins, hosted by northwest-trending tension fractures within metavolcanics and felsic intrusive rocks occur at the East, New East, and West Zones, at the Flambeau Lake Prospect, immediately north of Flambeau Lake.

The Flambeau Lake Prospect was optioned by Mr. A. Kozowy to Voyager Explorations Limited, who did linecutting, VLF-EM and magnetometer surveys, trenching, sampling, and geological mapping, followed by eight diamond-drill holes totaling 981 m (3220 feet), during 1983 and 1984. Four of the eight holes intersected narrow sections of gold mineralization assaying between 0.11 and 0.29 ounce gold per ton. All four holes were drilled in the vicinity of the East Zone (Assessment Files, Resident Geologist's Office, Kenora). The property was returned to Mr. Kozowy when Voyager Explorations subsequently dropped the option. Mr. Kozowy did more intensive prospecting and stripping on the property in early 1985, which led to the discovery of numerous high grade gold-bearing quartz veins at the East Zone. Kidd Creek Mines Limited optioned the property from Mr. Kozowy during the summer of 1985 and began an exploration program.

Quartz veins on the property are commonly composed of white quartz, orange-brown iron carbonate, black tourmaline and ≤1% disseminated pyrite with accessory sulphide minerals such as chalcopyrite, galena, and sphalerite. Wallrock alteration is characterized by pervasive silicification, pyritization, carbonatization, and sericitization. Alteration haloes occur around the quartz veins, where the most intense alteration is immediately adjacent to the veins and decreases abruptly about 10 cm or less on either side of the veins.

At the East Zone, located on the north shore of Flambeau Lake, quartz veins are hosted by a very wide zone of numerous, *en echelon*, northwest-trending tension fractures, crosscut by several narrow east-trending shears, within an intensely altered quartz-diorite stock containing abundant disseminated magnetite and a few narrow magnetite veinlets. The diorite has been intruded by a gabbro and east-trending mafic to intermediate dikes, crosscut by quartz-feldspar porphyry dikes. All rock types are intruded by quartz veins, although the veins are less numerous in the mafic rocks. This may be due to differences in rock competency, where the brittle felsic rocks fracture more readily during deformation than the more ductile mafic rocks. Significant gold mineralization is restricted to the quartz veins and does not occur within the altered wallrocks. Throughout the Flambeau Lake Prospect, veins hosted by felsic dikes are devoid of gold. Quartz veins within a "high-grade" trench on the East Zone host massive pyrite mineralization associated with chalcopyrite, galena, and sphalerite. A 100 pound sample, taken from the trench by Mr. A. Kozowy, assayed 1.7 ounces gold per ton (A. Kozowy, personal communication, 1985). Four grab samples, taken by the author from quartz veins in a number of trenches on the East Zone, assayed 0.02 ounce gold per ton, 3.86 ounces gold per ton with 4.88 ounces silver per ton, 0.17 ounce gold per ton, and 0.04 ounce gold per ton. Four grab samples of quartz vein material, taken by the author, from trenches 45 m east of the East Zone assayed between 0.03 and 0.04 ounce gold per ton (Geoscience Laboratories, Ontario Geological Survey, Toronto). Chip samples taken from various trenches on the East Zone by Voyager Explorations Limited assayed 0.088 ounce gold per ton over 2.7 m (9 feet), 0.089 ounce gold per ton over 2.4 m (8 feet), 0.103 ounce gold per ton over 1.8 m (6 feet), and 0.636 ounce gold per ton over 2.4 m (8 feet) (Assessment Files, Resident Geologist's Office, Kenora).

At the New East Zone, 245 m northwest of the East Zone, quartz veins are hosted by northwest-trending tension fractures, and east-, northeast-, and northwest-trending narrow shear zones within a second magnetite-bearing diorite stock. The diorite is intruded by a northwest-trending quartz-feldspar porphyry dike and east-trending intermediate to mafic dikes.

The wallrocks adjacent to the quartz veins are intensely pyritic and carbonatized; however, the majority of the diorite is weakly to moderately altered, because tension fractures and quartz veins are not as abundant as at the East Zone. Seven grab samples of quartz vein material taken by the author from 4 trenches on the zone assayed between <0.01 and 0.11 ounce gold per ton (Geoscience Laboratories, Ontario Geological Survey, Toronto).

The West Zone, located on the Ojibway Drive Road about 1 km west of the East Zone, consists of northwest-trending gold-bearing quartz veins crosscutting intense northeast-trending shear zones within massive, mafic, amygdaloidal flows. The mafic metavolcanics are intercalated with mylonitized, massive, intermediate to felsic flows intruded by northeast-trending intermediate to mafic dikes and a

small gabbro intrusion. The mafic dikes and deformed metavolcanics are crosscut by a northwest-trending quartz-feldspar porphyry dike. The quartz veins occur within tension fractures which have formed perpendicular to the dominant shear direction in the mafic metavolcanics, which is also crosscut by a quartz-feldspar porphyry dike. There is an obvious absence of quartz veins in the felsic metavolcanics, which suggests that the mylonitic style of deformation in the felsic rocks did not allow the formation of open tension fractures. The quartz veins host ≤1% disseminated pyrite and <1% chalcopyrite and associated malachite. Sheared metavolcanics, in a trench at the extreme west end of the zone, appear to be partially replaced by massive pyrite (≤50%) and have been tourmalinitized. A grab sample, taken by the author, from the sheared, pyritic (15%) metavolcanics assayed 495 ppb Au, while a grab sample, taken by the author, from a pyritic (2%) quartz vein in the same trench assayed 5360 ppb Au. A grab sample, taken by the author, from a quartz vein containing <1% pyrite and chalcopyrite, in the most easterly trench on the West Zone, assayed 1.52 ounces gold per ton with 56 ppm Cu (Geoscience Laboratories, Ontario Geological Survey, Toronto). A 4.8 m (16 feet) long chip sample, taken from the eastern trench by Voyager Explorations Limited, assayed 0.249 ounce gold per ton (Assessment Files, Resident Geologist's Office, Kenora).

Northwest-trending tension fractures hosting quartz veins occur throughout the Flambeau Lake area. Grab samples, taken by the author, from quartz veins in an intensely sheared and altered gabbroic to dioritic host rock, approximately 182 m (600 feet) east of Flambeau lake, assayed 0.01, 0.02, and 0.04 ounce gold per ton and 155 ppb Au, 5330 ppb Au, and 7640 ppb Au. A grab sample, taken from approximately the same location by Mr. A. Kozowy, assayed 0.229 ounce gold per ton (A. Kozowy, personal communication). Grab samples taken by the author from quartz veins in sheared and altered intermediate to felsic brecciated flows, 365 m (1200 feet) east of Flambeau Lake, assayed 160, 1250, 1640, and 3380 ppb Au (Geoscience Laboratories, Ontario Geological Survey, Toronto).

Summary and Conclusions

The gold occurrences in the Flambeau Lake-Larson Bay map area are confined to the Lower Wabigoon Volcanic Group where they are structurally controlled by east-trending, linear shear and fracture zones and by northwest-trending, *en echelon* tension fractures. These structures provided open conduits for the circulation of mineralized hydrothermal fluids which deposited gold. The tension fractures and shear zones have also controlled the emplacement of felsic dikes. Mafic dikes are controlled by east-trending structures. Long continuation of the regional stress regime is indicated by the emplacement of a later northwest-trending diabase dike which crosscuts the western half of the map area. The tension fractures and shear zones are regionally related to the Wabigoon Fault, in response to dextral movement along it. The abundance of quartz veins controlled by tension fractures in the Flambeau and Guy Lake area is due to the local abundance of felsic metavolcanics and intrusive rocks. The brittle nature of the felsic rocks has caused them to fracture during deformation while the mafic and intermediate rocks have sheared. The lack of felsic rocks in the eastern part of the map area, in the vicinity of Larson Bay, explains why most of the gold occurrences in that area are controlled by east-west shear zones. The presence of quartz veins crosscutting intense northeast-trending shear zones (West Zone) and of east-trending shears crosscutting gold-bearing quartz veins (East Zone), indicates a complex deformational history, developed over a long period of time, both pre- and post-dating gold mineralization.

Abundant disseminated magnetite within some of the country rocks hosting gold-bearing quartz veins (Flambeau Lake Prospect, Vanlas Prospect, League Prospect), may have served as a chemical trap for gold precipitation: sulphidation of magnetite by pyrite during the circulation of mineralized hydrothermal fluids through open fissures in the country rocks. Macdonald (1984) has suggested three processes to explain gold deposition within iron-rich rocks. Crystallization of gold from hydrothermal fluids may occur either by the plating of gold upon sulphide grains, or by the destabilization of gold in solution by a fall in fluid pH, caused by CO_2 loss during carbonate formation, or by the destabilization of gold in solution due to sulphur loss. Any or all of these processes may have operated at the Flambeau Lake Prospect, where abundant pyrite occurs within intensely carbonatized wallrocks, and where gold is restricted to quartz veins as visible gold, or associated with sulphide mineralization in the quartz veins.

The presence of numerous amygdaloidal dikes in the Flambeau Lake area may indicate their subvolcanic emplacement. At the East Zone, on the Flambeau Lake Prospect, the presence of autobrecciated felsic flows immediately adjacent to the quartz-diorite stock, which seem to merge into the stock, suggests that the stock is subvolcanic. However, implications for gold mineralization are unclear.

Many of the above conclusions are preliminary and may change during further field investigations anticipated for 1986.

Exploration Guidelines

Numerous gold occurrences consisting of single quartz veins or quartz stockworks within narrow shear zones have limited economic gold potential. Wide, east-trending zones of alteration, shearing, and fracturing may have better potential for gold, such as the zone which extends eastward from Pritchard Lake, in the vicinity of the Glatz Occurrence and Vanlas Prospect.

Wide fracture zones within felsic, magnetite-bearing intrusive rocks and felsic metavolcanics are also favourable targets due to their greater widths. Fractures within the host rocks provide abundant open fissures for the circulation of hydrothermal fluids, while the magnetite serves as a chemical trap for gold deposition. Sheared and fractured magnetite-bearing mafic intrusive rocks and metavolcanics are also good targets for the same reasons.

Gold-bearing quartz veins associated with magnetite-rich host rocks are not confined to the present map area but occur, for example, at the New Church Lake Occurrence in the Kawashegamuk Lake area, and at the Manhattan Occurrence and Lone Pine Prospect in the Eagle Lake area.

The quartz-diorite and gabbro intrusions at Flambeau Lake are represented by a magnetic high, centred on the East Zone of the Flambeau Lake Prospect. This type of magnetic signature can be readily identified on ODM-GSC Aeromagnetic Maps and can assist in locating other magnetite-rich intrusions, which may host gold mineralizaton associated with intense alteration, tension fractures and/or shear zones. Induced polarization surveys and/or very detailed magnetometer surveys may also assist in detecting zones of secondary sulphide enrichment which may host gold.

The stratigraphy in the map area is generally representative of the Lower Wabigoon Volcanic Group which extends eastward to Dinorwic Lake: the geology, according to Satterly (1943), consists of lenticular masses of felsic flows and agglomerates, some of which may be intrusive, intercalated with intermediate to mafic flows and agglomerates with widespread, but selective, iron carbonate alteration, where the felsic rocks are commonly fractured and altered to carbonate-sericite schists. These deformed and altered felsic rocks should be investigated for gold, as well as sheared and altered mafic metavolcanics.

DIAMOND DRILL CORE STORAGE PROGRAM

The core library program commenced in September 1985, and is intended to serve the three Northwestern Mining Divisions (Kenora, Patricia, and Red Lake). The building is currently (December 1985) under construction and due to be completed in early 1986. The library is staffed by C. Storey and C. Ravnaas.

Core collection in the Kenora area consisted of 287 m (940 feet) of core from the Kawashegamuk Lake area drilled by Labrador Exploration (Ontario) Limited. This deposit is described by Storey (1984) as a marble occurrence. During October, 1520 m (5000 feet) of core from the Sioux Narrows area was hauled to Kenora, and arrangements were made to obtain approximately 900 m (3000 feet) of other core from drilling north of Lobstick Bay, and another 1058.4 m of core from Bag Lake. Another 738 m (2420 feet) of mineralized and sampled core, drilled by Tasu Resources, was obtained from storage at Clearwater Bay, and arrangements were made to pick up what remains at their drill location on Eagle Lake. Core collection in the Sioux Lookout area is being handled under a Special Employment Program by the Sioux Lookout Resident Geologist; approximately 15 000 m is being collected. At Red Lake, an undetermined amount (possibly 2000 m) of core is in storage, and an additional 1470 m (4820 feet) was recovered from insecure storage in Cochenour.

In addition to this core, a large amount currently in storage at the three resident geologists' offices is being inventoried in preparation for transfer to the core library when the building is completed. Approximately 34 000 m of core will be available for examination when the facility opens.

Since the beginning of September 1985, there have been six direct inquiries about the core library from the mining industry, and two requests to examine core already in storage.

ONTARIO GEOLOGICAL SURVEY ACTIVITIES

During the 1985 field season, the following field parties from the Precambrian Geology and Mineral Deposits Sections operated within the Kenora Mining Division:

J.A. Ayer (Precambrian Geology Section) carried out detailed mapping of the Rat Portage Bay Area, Lake of the Woods, thereby completing a two-year program commenced in 1984 in the Bigstone Bay area (Figure 1.2, location A).

G.W. Johns (Precambrian Geology Section) continued a synoptic survey designed to provide a regional synthesis of geological data in the Gibi Lake-Kakagi Lake-Rowan Lake area (Figure 1.2, location B).

P.M. Smith (Mineral Deposits Section) conducted a detailed study of the geological setting of the Duport Gold Mine, Shoal Lake (Figure 1.2, location C).

ONTARIO MINERAL EXPLORATION PROGRAM (OMEP)

As of the end of November 1985, 82 designated OMEP programs, conducted by 65 companies, and on which a total of $4.96 million of assistance is anticipated, were operative in Kenora Mining Division.

RESEARCH BY OTHER AGENCIES

UNIVERSITY THESES

Geological theses related to the Kenora Mining Division believed to be in progress or completed during 1985 are as follows:

Masters Theses

Melling, D.: Completed a study of the geological setting and genesis of the Cameron Lake gold deposit of Nuinsco Resources Limited (Carleton University).

Smith, P.M.: Commenced a study of the geological setting of the Duport Gold Mine of Consolidated Professor Mines Limited, at Shoal Lake (University of Waterloo).

Stix, John: Completed a study of the transition from lower tholeiitic through to upper calc-alkaline volcanic rocks at Andrew Bay, Lake of the Woods, entitled "Volcanic Facies and Geochemistry of Archean Lava Flows and Pyroclastic Rocks near Kenora, Ontario, Canada" (University of Toronto).

Doctoral Theses

Edwards, G.R.: Completed a study of Archean volcanic, subvolcanic, and plutonic rock petrogenesis in the Kagagi-Pipestone Lakes area (University of Western Ontario).

ONTARIO GEOSCIENCE RESEARCH GRANT PROGRAM

D.M. Watkinson and D. Melling, Carleton University, completed a study of the geological setting and genesis of the Cameron Lake gold deposit.

OTHER RESEARCH

Don Davis, of the Royal Ontario Museum, continued his general interest in geochronological investigations in the Kenora Mining Division, and collected samples from the Shoal Lake area, and Mulcahy Lake, the latter in conjunction with Nuno Machado, also of the Royal Ontario Museum.

Professor H.C. Palmer, University of Western Ontario, initiated rock magnetic studies in the Mulcahy Lake Intrusion, near Eagle Lake.

A number of individuals, including K.H. Poulsen, of the Geological Survey of Canada, Warren Day, of the United States Geological Survey, and S.B. Shirey, of the Carnegie Institute of Washington, continued their research along the Wabigoon-Quetico subprovince boundary in the Fort Frances-Mine Centre area.

Personnel under contract to the Geological Survey of Canada carried out a study of fracture patterns in the Dryberry Batholith.

Graduate students under the general direction of Professor D. Perkins, University of North Dakota, conducted field studies in the vicinity of Highway 105, west of Lac Seul, as part of a continuing program of research into metamorphism and crustal genesis in the English River Subprovince.

Cameron Lake, the site of ongoing gold exploration, has been chosen by the Geoscience Working Group, an ad-hoc subcommittee of the Canadian Advisory Council on Remote Sensing, for special study. In 1985 geobotanical investigations were initiated, under the general coordination of D. Horler.

[2]Resource Geologist, Ontario Ministry of Northern Development and Mines, Red Lake

INTRODUCTION

After the exceptionally high 1984 claim staking activity, 1985 was a return to normal levels of claim staking. However, the number of claims recorded in 1984 (second only to 1969 when claim staking was high due to the discovery of the South Bay Base metal deposit) has translated into a two-fold increase in assessment work credits for the current year. The amount of work recorded in 1985 is second only to that performed in 1970.

Table 2.1 shows that exploration methods for gold and base metals have not changed substantially over the years. The proportions of diamond drilling, geophysics, geology, and other work (including stripping, trenching, prospecting, and geochemistry) performed for assessment work credits has remained essentially constant, even though base metals were the focus of exploration in 1970 and gold dominated exploration activity during 1984-1985. These statistics are misleading because much of the work performed in gold exploration is not filed for assessment credits. This work includes stripping, trenching, prospecting, and geochemistry. Thus, as expected, exploration companies are increasing the amount of prospecting and stripping in the search for gold mineralization.

The Birch Lake area, where most of the activity is taking place, was largely unstaked in early 1984. In contrast to other reasonably accessible greenstone belts in the province which underwent very active staking in 1981, 1982, and 1983, the Birch Lake area remained relatively inactive. Thus, in 1984, the Birch Lake area still had large tracts of favourable ground open for staking. Presently, the eastern half of the Birch Lake area is tightly staked while the remainder of the Birch-Confederation Lakes greenstone belt is only 20% covered by active claims.

The Red Lake camp is also undergoing a revival. Projected production at the Campbell Red Lake Mine in 1985 will reach a new high, probably 20 000 ounces more than 1984. The Arthur W. White Mine, formerly the Dickenson Mine, has maintained production in excess of 60 000 ounces per year for the past three years and has substantially increased its ore reserves. An air of optimism surrounds the underground exploration program on the McFinley Red Lake Mines Limited property; Jamie Frontier Resources Incorporated continued its underground exploration at the Mount Jamie mine and Esso Minerals Canada continued its underground exploration of the Cochenour mine for most of this year. A common thread to many exploration programs is the re-evaluation of major prospects and past producers where significant amounts of gold were discovered but never completely explored and evaluated. Successful efforts are being made to consolidate land packages and resume exploration on dormant patented properties.

The current optimism generated by the activity in Red Lake is counterbalanced by the impending closure of the Griffith iron ore mine south of Red Lake. During peak production, this mine had over 500 employees. Other than depressed iron markets and the low cost international iron production, the major factors causing this closure are the cost of hydro, natural gas, and rail transportation. Despite the impending closure of the Griffith mine, iron "ore" reserves remain at 41 million tons.

RESIDENT GEOLOGIST STAFF ACTIVITIES

In 1985, the office of the Resident Geologist was staffed by M.J. Lavigne, Resident Geologist; and B.T. Atkinson, Resource Geologist. Summer and fall support staff consisted of L. Zagozewski, geological assistant; and K. Boylen, computer clerk. Occasional assistance was also provided by H. MacDonald-Craig (Ministry of Natural Resources) for computer installation and programming and by Katimavik youths for field work.

Increased exploration activity and Ontario Geological Survey activity has dictated that much time was spent making property visits, leading field trips, and participating in field trips. Atkinson and Lavigne participated in the Institute on Lake Superior Geology Conference and field trip in May, at which Lavigne presented a paper on the geology and gold deposits of the Geraldton-Beardmore greenstone belt. After discussions with the Ear Falls Economic Development Advisory Group on the possibilities of economic stimulation of the Ear Falls area by the mining sector, several propositions were made and implemented by the Ministry of Natural Resources. These include geologic mapping on Birch Lake, a gold study in the Uchi-Confederation Lakes area, and a prospecting course. This 12-week course was given by Atkinson in cooperation with Confederation College in Ear Falls and was well attended. Similar interactions are also underway with the Red Lake Economic Development Corporation.

Lavigne began a mapping project, at a scale of 1 inch to 400 feet, over the area between Snib Lake and Howey Bay of Red Lake. This area contains the Howey, Hasaga and Red Lake Gold Shore mines as well as the Buffalo prospect. The initial emphasis will be on structure and its relationship to gold mineralization, followed by a lithogeochemical alteration study. Atkinson has begun detailed mapping of poorly recorded gold prospects in the Red Lake area. In preparation for the Red Lake field trip of the GOLD '86 Conference, to be held September 1986 in Toronto, Lavigne has been stripping and mapping outcrops in detail, as well as sampling for lithogeochemical analysis and thin sections. Several youths from the Katimavik program provided field support. A computerized indexing system for the assessment files is now 35% complete. This program was funded by

Experience '85 and the data input was done by Boylen. In cooperation with the Mineral Deposits Section of the Ontario Geological Survey, Lavigne has completed his investigations on the application of sulphur isotopes on mine scale gold exploration.

In addition to leading field trips in Red Lake for many mining company groups, several university researchers, and government geologists, field trips were also given to Katimavik youths, Junior Rangers, Ministry of Natural Resources personnel, and the Mesabi Range Geological Society.

In 1985, the following occurrences, prospects, past producers, and mines were visited by the staff of the Red Lake Resident Geologist Office:

1. Bathurst Mine, Skinner Township
2. Price-Logan Prospect, Skinner Township
3. Consolidated Shunsby Occurrence, Skinner Township
4. Dickenson Mines Prospect, North Spirit Lake
5. Silver Spirit Mines Occurrence, North Spirit Lake
6. Upper Canada Mines Occurrence, North Spirit Lake
7. G. Desmeules Occurrence, North Spirit Lake
8. Spirit Lake Mines Occurrence, North Spirit Lake
9. BP Selco Property, North Spirit Lake
10. St. Joe; South Greencamp Occurrence, Birch Lake
11. St. Joe; Greencamp Occurrence, Birch Lake
12. St. Joe; Horseshoe Island Prospect, Birch Lake
13. Beakhouse Occurrence, Birch Lake
14. Springpole Portage Occurrence, Birch Lake
15. Kidd Creek; MacGregor Occurrence, Birch Lake
16. Kidd Creek; MacKenzie Red Lake Gold Mines-Hansen Option, Birch Lake
17. Titus Keewaycabo Occurrence, Shabumeni Lake
18. Sol D'Or Mine, Grace Lake
19. Shabumeni-Dome Occurrence, Shabumeni Lake
20. Jackson Manion Mine (Orofino), Dent Township
21. Uchi Mine (Lac), Earngey Township
22. Master Resources and Development Property, Favourable Lake
23. W. Drosdoski Property, Heyson Township
24. Goldquest; Lassie Prospect, Balmer Township
25. Goldquest; MacMarmac Property, Dome Township
26. Alcourt Prospect, Fairlie Township
27. Sandy Creek Pegmatite Beryl Prospect, Ear Falls
28. Campbell Red Lake Mine, Balmer Township
29. Arthur W. White Mine, Balmer Township
30. McFinley Mine, Bateman Township
31. Mount Jamie Mine, Todd Township
32. Griffith Mine, Bruce Lake.

From these property visits, some interesting observations were made and unexpected gold assays produced. The Bathurst mine, a past producer, is located between Car and Bathurst Lakes in Skinner Township. The property consists of 12 leased claims. Several observations made at this site do not conform with those made on gold deposits in general. Firstly, the mineralization, which consists of sulphide and carbonate-poor fissure filling quartz veins, is hosted by amphibolite grade gabbro, pillowed magnesium tholeiites, and felsic dikes. This is inconsistent with the preponderance of gold mineralization which occurs as sulphide impregnations when hosted by amphibolite grade rocks.

Secondly, despite evidence for high fluid flow in a 0.5 square mile area, evidenced by abundant large quartz veins with visible gold, the country rock has undergone no visible alteration. The only visible alteration is in the immediate wallrock which has been sheared and sulphidized. Of the five veins examined, three easily yielded visible gold. One of these veins, the #5 vein, has an uncovered maximum width of 10 feet. The lack of wallrock alteration in such close proximity to abundant gold mineralization produces some doubt on the effectiveness of lithogeochemistry as an exploration tool. Although its usefulness has been demonstrated in many Archean gold camps, the variability in intensity and types of alteration associated with gold mineralization suggest that one must proceed with caution and integrate this tool with other exploration methods.

The Price-Logan property, a dormant group of four patented claims on the eastern boundary of the Bathurst property, was also visited. The mineralization consists of a sulphide impregnated, talcose, east-west trending shear zone containing isolated quartz lenses. This mineralization is exposed for about 1/4 mile, from the northeastern corner of Car Lake. Excellent exposure was provided by deep wide pits. The host rock is unaltered pillowed magnesium tholeiite. Three grab samples from this zone assayed 0.014, 0.22, and 0.54 ounce gold per ton.

An impressive looking, highly sheared, altered, and sulphidized lean iron formation at the southwestern end of Birch Lake does not contain gold. Three analyses taken from the Beakhouse occurrence produced the following gold values: 4 ppb, 2 ppb, and <2 ppb. The pyrite in these sediments occurs as rods at the bedding-cleavage intersection. Relict jasperoid chert beds have been reduced to a light pink colour and no magnetite was found interbedded. This mineralization is considered anomalous by the authors since despite the alteration, shearing, and sulphide content, no gold is present.

Another anomalous association was observed on the western side of South Bay of Birch Lake. Gold mineralization at both the Greencamp and South Greencamp occurrences is associated with wide calcite veins and not the ankeritic veins normally associated with gold mineralization. The calcite veins, one of which is 6 feet wide, trend 110° and are enclosed in well bedded wackes trending 150°. No evidence was found to support the alternative hypothesis, that the calcite represents a shear-transposed carbonate sediment. Two assays taken by the authors from an isolated 2-inch quartz vein from this location ran 2.42 and 0.24 ounces gold per ton. The calcite veins have a gold content in the low ppb range.

EXPLORATION ACTIVITY

The Red Lake Mining Division is currently undergoing the second highest level of exploration activity since 1955. This level has been surpassed only by that which occurred in 1970, shortly after the discovery of the South Bay base-metal deposit. The only other time when exploration activity may have been more active was during the initial staking rush of 1926. Although the staking level was high in 1926, the amount of work performed cannot be accurately determined.

This current activity is centred in two areas: grass roots dominated exploration in the Birch Lake area; and surface and underground exploration of past producers and prospects in the Red Lake area. Activity in the Confederation Lake area is not as intense and consists of re-examination of past producers as well grass roots exploration. Except for two mining companies which are looking for base metals and gold, all exploration programs are gold oriented.

Four underground exploration programs were active in Red Lake in 1985.

At the Rowan Lake mine, Goldquest Exploration Incorporated drilled 51 holes for a total of 14 895 feet. Within the main vein, 49 500 tons of ore grade material has now been outlined. The grade is 0.74 ounce gold per ton (uncut) and 0.42 ounce gold per ton (cut). Production from this site is dependent on road development, access to hydroelectric power, and the price of gold.

Jamie Frontier Resources Incorporated drilled just over 100 holes, totaling approximately 16 000 feet at the Mount Jamie mine. Results, as reported by The Northern Miner over the year have been encouraging. This drilling has added to the reserves which are in excess of 20 000 tons, grading 0.87 ounce gold per ton over an average width of 4 feet (The Northern Miner, May 2, 1985).

Esso Minerals Canada, after completing more than 50 000 feet of diamond drilling, suspended underground exploration in October at the Wilanour Resources Limited property. The underground drilling program tested the possible down dip extensions of the Annco Zone and the Wilmar Breccia Zone. Drilling consisted of long holes (in excess of 2000 feet) below the 2050-foot level. Although the holes intersected the mineralized zones, the results are considered uneconomic by the company. A 10 000-foot surface diamond drilling program tested several targets and was completed in December. Esso Minerals Canada now has in excess of a 60% working interest in the mineral rights.

SUMMARY OF CLAIMS RECORDED AND ASSESSMENT WORK CREDIT

McFinley Red Lake Mines Limited, in partnership with Phoenix Gold Mines Limited (42.9%) and the Coniagas Mines Limited (7.1%), continued to explore its property. Approximately 25 000 feet of diamond drilling and 2200 feet of drifting was done on the 150- and 400-foot levels. Several potential ore lenses have been identified and drifting often encounters high grade gold mineralization (The Northern Miner, October 21, 1985).

Outside the Red Lake area, other past producers are being evaluated. Lac Minerals Limited is exploring the Uchi Mine, east of Confederation Lake. Their program in 1985 consisted of an I.P. survey, soil sampling, geologic mapping, and relogging drill core. West of Confederation Lake, Orofino Resources Limited has been drilling on the Jackson-Manion Mine. Noranda Incorporated is examining the Jason (Argosy) mine area on Casummit Lake, with a program consisting of a magnetometer survey, trenching, sampling, and geologic mapping.

Several properties in the Red Lake area were drilled in 1985. The most extensive drilling program was carried out by Goldquest Exploration Incorporated on four of its properties. The Inore group had 16 holes for a total of 8041 feet; the Abino property had 8 holes for a total of 4957 feet; the South East group had 3 holes for a total of 2011 feet; and the Kilbarry property had 5 holes for a total of 2696 feet.

Campbell Red Lake Mines Limited drilled 15 000 feet on the adjacent Craibbee-Fletcher property and reported no values of economic significance.

Outside the Red Lake area, several drilling programs were carried out. Dome Mines Limited drilled in Corless and Honeywell Townships and in the Birch-Angela Lakes area. Massive Energy Limited drilled on its Borland Lake property. St. Joe Canada Incorporated did 7792 feet of drilling on their Horseshoe Island prospect and on occurrences in the vicinity of South Bay of Birch Lake. BP Selco has drilled 11 holes for a total of 3964 feet at 5 locations from Bruce Lake to Birch Lake. Eldor Resources Limited has done 575 feet of drilling on the Kippen Lake property; Noranda Incorporated has drilled on the Dixie Lake area property; and Golden Terrace Resources Corporation has drilled their property at Casummit Lake.

A joint venture partnership with Temulac Holdings as the operator began tailings reclamation in Madsen. To date, they have processed the overflow pond next to the Madsen mill and have run a five-ton test sample from the main tailings ponds with satisfactory results. Reclamation of the tailings pond will continue in Spring, 1986.

ONTARIO GEOLOGICAL SURVEY ACTIVITIES

A.J. Andrews and H. Hugon (University of Toronto) continued their study of the relationships of gold mineralization to metamorphism, alteration, and structure. After several years of investigating regional relationships, this year's emphasis was on the Arthur W. White and Campbell Red Lake Mines.

A.J. Fyon and L. Lane commenced a two-year study of gold mineralization in the Confederation Lake area. Initial emphasis was on regional alteration patterns and structural relationships, and a detailed documentation of past producers.

Gary P. Beakhouse mapped the western half of the Birch Lake area while D.J. Good mapped the

3. Sioux Lookout Resident Geologist Area, Northwestern Region

D.A. Janes

Resident Geologist, Ontario Ministry of Northern Development and Mines, Sioux Lookout

INTRODUCTION

The Sioux Lookout office is presently staffed by D.A. Janes, Resident Geologist and M.O. Sawtelle, Geological Secretary. The position of Resource Geologist is vacant. Mr. Roy Sooner is the Mining Recorder for the Patricia Mining Division and Mrs. D. Cosco is the Chief Clerk.

During 1985, a number of contract staff were employed in a variety of tasks. Mr. R.J. Redden was employed as geologist to prepare Geological Data Inventory Folios. Students, C. Bath and J. Burnell, carried out various office and field duties during the summer months. Mr. B. Bowen and two assistants conducted a drill core retrieval program during the Spring and Fall of the year. This program is jointly funded by Employment and Immigration Canada and the Ontario Ministry of Natural Resources, under the Resources Sector Work Program.

Mr. Richard Trotter conducted an evaluation of geophysical methods for aggregate exploration and inventory in the vicinity of the town of Sioux Lookout. This study was designed to develop efficient, locally applicable exploration techniques in areas of limited coarse aggregate supply.

Mineral exploration activity in the Patricia Mining Division continues the trend of the past two years in that most work is directed towards gold exploration (Figures 3.1 and 3.2). Activity in the Pickle Lake area is most intense and is centred around Dome Mines' Dona Lake project. The North Caribou Volcanic Belt is also very active with most work done on the Agutua Arm and Opapimiskan Lake areas. A considerable amount of exploration has been done north of Lake St. Joseph, between the Obaskaka Lake Pluton and Bancroft Lake to the east. Several programs were carried out in the Fry-Bamaji Lakes area. Less intense but significant activity continues on north Sturgeon Lake and on Minnitaki Lake in the vicinity of Goldlund Mine. Programs directed toward platinoid metals have been started in the north of the Division.

The Mattabi and Lyon Lake Mines on Sturgeon Lake continued in Froduction through 1985. Thierry Mine (UMEX Incorporated) at Pickle Lake remained in care and maintenance during 1985. Goldlund Mine in Echo Township shut down in the Spring of 1985. The mill is intact and could be reactivated quickly. The Musselwhite Consortium (Dome Mines operator) completed their underground evaluation of the Opapimiskan Lake property. The decline is bulkheaded and has been allowed to flood. Dome Mines Limited continued advanced exploration on their Dona Lake property near Pickle Lake and are sinking shaft as this report is written.

RESIDENT GEOLOGIST'S ACTIVITIES

The Resident Geologist's program was constrained during 1985 by the lack of a Resource Geologist, the absence of a trained geological secretary during the field season, and generally deplorable weather across the northwest of Ontario. These factors limited field time and reduced other activities.

All operating and shut-down mines within the Division were visited at least once. Two weeks were spent on visits to Sturgeon Lake and Minnitaki Lake properties. One week was spent on a visit to Wunnummin Lake in company with G. Stott and H. Wallace of the Ontario Geological Survey. The results of this visit are reported *in* Stott and Janes (1985).

Core cataloguing was done for the Sioux Lookout core retrieval program. At year end, approximately 30 500 m of exploration core was stored securely at a temporary facility in Sioux Lookout. Most of this core will be moved to the Regional Core Library in Kenora when completed.

Several lectures were given at local secondary schools by the Resident Geologist. Two Junior Ranger lectures and field trips were held. The Geological staff developed and presented a display at the Blueberry Festival, an annual trade fair in Sioux Lookout.

The Resident Geologist participated in a field trip for the Institute of Lake Superior Geology in May, 1985. Several papers dealing with local geology were co-authored with members of the Ontario Geological Survey and the Ontario Centre for Remote Sensing.

To partially replace a resident economic geologist, the Sioux Lookout office partially funded an economic geologist for an Ontario Geological Survey party which mapped a portion of Lake St. Joseph. This work is reported in Kay and Stott (1985).

Technical and logistical support was provided to several graduate students of the University of North Dakota. They are conducting studies on a gold property in the Wabigoon Volcanic Belt and studies on metamorphism in the English River Gneissic Subprovince. Three graduate theses have resulted from these studies and two others are in progress.

ONTARIO GEOLOGICAL SURVEY MAPPING PROGRAMS

The Ontario Geological Survey carried out two major programs within the Patricia Mining Division during 1985. The larger program, a multidisciplinary study of the North Caribou Lake Volcanic Belt, is in the second year of a three-year program. The coordinated study includes Precambrian mapping at the one inch to quarter mile scale, detailed mapping of mineral deposits and Pleistocene mapping. This program is integrated with geophysical and isotopic age studies. Current results are summarized in F.W. Breaks *et al.* (1985) and in Piroshco and Shields (1985).

The results to date of this program have been very interesting, and more importantly, have provided the basis for a number of well conceived exploration programs throughout the area. While exploration may have occurred without this program, it provided an opportunity to bypass much of the "grass-roots"

phase and to progress to property and detailed exploration.

The second Precambrian mapping program was located in the Lake St. Joseph portion of the Uchi Volcanic Subprovince and was led by G. Stott. This work is part of a multi-year program to map the Uchi Volcanic Province within the Patricia Mining Division. While not as broadly based as the North Caribou project, it has integrated economic and geophysical studies and has had a considerable stimulative effect on exploration in the area.

MINING ACTIVITY

Mattabi Mines Limited and Noranda Mines Limited, Lyon Lake Division, are located on Sturgeon Lake. The Mattabi Mine is owned by Noranda Mines Limited (60%) and Abitibi-Price Incorporated (40%). Ore from both the Lyon Lake and Mattabi Mines is processed at the Mattabi mill to produce zinc, copper, and lead concentrates. Production was down from 1983-1984 levels due, in part, to a strike during the Summer of 1985. The mine is projected to employ 350 workers in 1986 and will mill approximately one million tons, 60% of which will be mined at Mattabi and the remainder at Lyon Lake.

Thierry Mine (UMEX Incorporated) at Pickle Lake remained under care and maintenance during 1985. The mine formerly produced copper-nickel concentrate from a high grade zone in a layered mafic complex. Gold, silver, and platinoid values were present in the concentrate.

Goldlund Mine in Echo Township shut down in the Spring of 1985. During shut-down, the mill produced a combined gravity-float gold concentrate from a mill rated from 300 to 400 tons per day. A smaller, parallel circuit was capable of producing 100 tons per day and was dedicated to custom milling. The mill produced in excess of 15 000 troy ounces of gold in approximately 1 1/2 years of production from one level, serviced by decline and from a small open pit. The mine exhausted developed ore and was unable to raise funds to continue with underground development. The underground machinery was removed and the mill mothballed before shut-down.

DEVELOPMENT PROJECTS

The Musselwhite Consortium (Dome Mines operator) completed a decline on their Opapimiskan Lake property during 1984. Underground mapping and bulk sampling studies indicated a mineral inventory of some three million tons of gold-bearing iron formation. The grade was not considered economic at present prices. The Consortium carried out a drilling program in 1985 to evaluate new zones. The decline was sealed off and allowed to flood.

Dome Mines continued exploration of their Dona Lake property, 11 km south of Pickle Lake. The mineralization is gold contained in sulphide zones within folded altered iron formation. Dome Mines reported a drill-indicated ore reserve of 1.3MM short tons at 0.22 troy ounce per ton. A work site was cleared in 1985. It is intended to sink to 175 m with drifts at the 100- and 160-metre levels. A bulk sample will be taken for metallurgical tests and grade estimation. The development is very favourably sited near the town of Pickle Lake, can be serviced by electricity form the existing grid, and should have no problem housing employees.

MINERAL EXPLORATION ACTIVITY

The past year has been a very good one for exploration in Patricia Mining Divison (Tables 3.1 and 3.2). Total man days of assessment credit reported for 11 months will match the peak year of 1981 and the exploration expenditures will exceed 12 million dollars (Table 3.3). While claim staking is down compared to 1983-1984, the claims active should be near the 10 000 mark. Diamond drilling days reached a 12-year high and other exploration indicators are at high levels. Considering that very little base-metals exploration has been done, these are excellent results. An encouraging aspect of exploration in the Patricia Mining Division is that a large portion of exploration is taking place in the northern, less accessible belts such as Big Trout Lake, North Caribou Lake, and the Uchi Subprovince. This trend is due to the recognition of the potential of iron formation related gold mineralization. Another contributing factor is a good mixture of seasoned major mining companies and highly active junior exploration groups, largely based on the Vancouver Exchange.

Unfortunately, base-metal exploration remains at a very low level. Cumberland Resources Limited and UMEX Incorporated continued exploration in the Evans Lake base-metal area. UMEX Incorporated carried out dual purpose exploratory studies in several areas and several companies did exploratory work in the Meen Lake, Fry Lake, and Dempster Lake areas. However, the total is <10% of the effort expended on precious metals.

Some renewed interest was shown in the platinoid metals. One drilling project was done in late fall on the Big Trout Lake layered complex, but results have not been released. Little, if any, exploration for granitoid based mineralization was done in 1985.

The influence of the Ontario Mineral Assistance Program is shown in many of the northern based gold exploration programs. Table 3.4 indicates the number of programs based widely but predominantly in the northern portion of the mining division. Approximately 5 million dollars of eligible expenditures are involved with a possible pay-back of 1.25 million dollars. Taking into account that only non-producing companies are eligible, the amounts are impressive.

Several groups and companies have been especially active in the Pickle Lake and North Caribou Lake areas. Companies associated with Mr. H. Hodge, such as Van Horne Gold Exploration Incorporated and Moss Resources Limited, have put together a grass-roots exploration program in the Pickle Lake, North Caribou Lake, and Bancroft Lake areas. The companies have acquired and worked on known occurrences and discovered new areas of gold mineralization, largely based on shear zone hosted and iron formation related deposits. This is the third year that these associated companies have mounted major programs and a number of their properties have been drill tested. The most interesting program to

49	Umex Inc.	Beckington Lake - DD-12-8619.7', Geoch, CS, Geophys, GL in 1984/85; Evans Lake - Geoch, A. CS, DD-5-1534.8' in 1984/85; Ponsford Lake - DD-7-3319' in 1970

date has been the discovery and drilling of an area near the Musselwhite Consortium Deposit on Opapimiskan Lake. Good gold intersections were obtained on the northern shore of the lake in altered magnetic iron formation folded into north-plunging antiforms.

The Dunlop Grubstake, a group of young geologists from Vancouver, ran an exploration program in 1984 and 1985 which resulted in their acquiring a number of new prospects in the North Caribou and Meen-Dempster Lakes areas. These properties have been acquired by the Northern Dynasty Exploration Limited for further exploration.

The author is encouraged by the programs described above since, in many cases, the properties were acquired on the basis of good geological work and involved new prospects, rather than a reactivation of known properties.

Falconbridge Limited continued an exploratory program on the Armstrong-Best properties on King Bay of Sturgeon Lake. They have optioned other properties in the area and have a drilling and geological program in progress.

Camreco Incorporated and Tarbush Lode Mining Limited hold properties near Goldlund Mine in Echo Township. Tarbush Lode Mining Limited has run a drilling and exploratory program for the past two years on their properties. Most recently they evaluated the Eaglelund prospect north of Goldlund Mine.

TABLE 3.2 SUMMARY OF CLAIMS RECORDED AND ASSESSMENT WORK CREDIT

* Corrected figures of 1984 (additional work not shown is included in the Total Man Days)

** 1985 figures up to and including November (additional work not shown is included in Total Man Days)

Year	Claims Recorded	Claims Cancelled	Claims Active	Diamond Drilling (Man Days)	Geophysical Surveys (Man Days)	Geological Surveys (Man Days)	Total Man Days
1974	1,011	3,223	5,659	38,049.0	6,255	102	44,406
1975	1,019	2,489	3,903	38,492.7	18,953	1,858	59,303.7

TABLE 3.3 **ASSESSMENT WORK AND OTHER INFORMATION RECEIVED.**

Abbreviations for Tables Used in this Report

AEM - Airborne Electromagnetic Survey
A Mag - Airborne Magnetometer Survey
Assess - Assessment Work
BM - Base Metal
CS - Core Samples
DD - Diamond Drilling(numbers following "DD" indicate the number of holes drilled and total length drilled respectively)
DDH - Diamond Drill Holes
EM - Electromagnetic Survey
Geochem - Geochemical Survey
Geophys - Geophysical Survey
GL - Geological Survey
IP - Induced Polarization Survey
Mag - Magnetometer Survey
OMEP - Ontario Mineral Exploration Program
OVD - Overburden Drilling
SA - Sampling, Assays
STD - Soils Test Drilling
STr - Stripping, Soil Trenching
Tr - Trenching
VLF - Very Low Frequency

RECOMMENDATION FOR EXPLORATION

Since at least half the exploration effort in the Patricia Mining Division has been directed towards gold in magnetic iron formation, it hardly seems necessary to make the point of the value of this exploration target.

The Wabigoon Subprovince has not shown much promise for this type of gold deposit but the Uchi and Sachigo Subprovinces have a number of showings and prospects.

Wunnummin Lake has been visited and does not appear to be similar to North Caribou Lake. An appropriate exploration tool would appear to be lake sediment sampling for this little known belt.

4. Thunder Bay Resident Geologist Area, North Central Region

G.C. Patterson[1], J.K. Mason[2], and B.R. Schnieders[2]

[1]Resident Geologist, Ontario Ministry of Northern Development and Mines, Thunder Bay

[2]Economic Geologist, Ontario Ministry of Northern Development and Mines, Thunder Bay

INTRODUCTION

Current permanent staff in the Thunder Bay Office include: K.G. Fenwick, Regional Mineral Resources Co-ordinator; J.F. Scott, Resource Geologist; and A.R. Dowton, Secretary. The remainder of the staff held contract positions. F.J. Kristjansson, Quaternary Geologist, was responsible for geological input to land use concerns (such as Forest Management Agreements and Municipal Planning) and aggregate mapping. The Beardmore-Geraldton Economic Geologist Program was supervised by J.K. Mason, Resource Geologist, with assistance from G.D. White, Resource Geologist. B.R. Schnieders, Resource Geologist, with assistance from A.A. Speed and Mike Hine, Resource Geologists, ran the Economic Geologist Program in the Schreiber-Terrace Bay area. M.C. Kennedy, Resource Geologist, with assistance from P.M. Gertzbein, Resource Geologist, continued a Building Stone Inventory of the North Central Region. A.D. MacTavish and R.J.A. Dutka, Resource Geologists, ran a Cobalt-Base Metal-Platinum Group Elements Study in the Atikokan area. P. Perry and T. Twomey, Resource Geologists, prepared Geological Data Inventory Folios. S. Koski supervised the Assessment Files. J. Seguin, Senior Assistant, aided J.F. Scott in mapping MacGregor Township. R. Larson and M. Hine were contracted to give Junior Forest Ranger talks. D. Parker and C. Vranjkovic worked as Experience '85 students. Four Mining Sector Work Programs with a staff of 18 were run in 1985. G.D. White, Drill Core Library Geologist and P. Hinz, Assistant Core Library Geologist, have been hired to run the newly constructed Thunder Bay Drill Core Library.

ACKNOWLEDGMENTS

The section in this report on Quaternary Geology was written by F.J. Kristjansson. The description of the Schreiber-Terrace Bay Economic Geologist Program was written by B.R. Schnieders with assistance from A.A. Speed. J.K. Mason, with help from G.D. White, wrote the section on the Beardmore-Geraldton Economic Geologist Program. The report on the Cobalt-Base Metal-Platinum Group Elements Study in the Atikokan area was written by A.D. MacTavish and R.J.A. Dutka. M.C. Kennedy and P.M. Gertzbein contributed the section on Building Stone in the North Central Region. G.D. White and P. Hinz wrote the section dealing with the activities of the Core Library. Technical support was provided by S. Koski, P. Perry, and A.R. Dowton.

RESIDENT GEOLOGIST STAFF ACTIVITIES

Much of the Resident Geologist staff's time was spent in consultation with prospectors and with geologists from exploration and mining companies (an average of 12 consultations a day). Other activities included field trips, tours, and property visits.

The Hemlo area remained very active. The Resident Geologist gave a total of six talks on the Hemlo deposit to various groups and organizations and three field trips were given. In addition, approximately three weeks were spent in the area carrying out field research. A section of the 1985 Canadian Institute of Mining and Metallurgy-Geological Association of Canada Field Trip Guide to Hemlo was written. Approximately twenty 10-minute interviews on various topics in mining were given to CBC Radio Noon, aired in Northern Ontario. A number of silver properties in the Thunder Bay area were visited. A paper on "Amethyst in Ontario" was written and published in the Canadian Gemologist. A course on prospecting was given through Confederation College, Thunder Bay.

J.K. Mason gave seven tours in the Beardmore-Geraldton area. A Field Trip Guide of this area was published (Mason *et al.* 1985). B.R. Schnieders led five tours in the Schreiber-Terrace Bay area. Property visits and reports of the Atikokan Economic Geologist. Open File Report 5539 by B.R. Schnieders and R.J.A. Dutka, was published. Four poster displays were presented at the Ontario Geological Survey's Geoscience Research Seminar and Open House, 1985, Toronto.

K.G. Fenwick carried out field examinations of hazard land locations throughout the region, as well as compiling historical data on early mining in the area.

J.F. Scott, with assistance from J. Seguin, completed the mapping of MacGregor Township.

Geological staff, particularly F.J. Kristjansson, continued to be involved in land use planning, mining exploration in candidate parks, forest management agreements, environmental issues, and road placements. A number of townships were given assistance in assessing aggregate potential. Several public meetings concerning aggregate assessment were attended.

Four Mining Sector Work Programs, employing a total of 18 people, were organized and supervised through this office. These included locating hazard land sites, updating mineral deposit files, preparing overlays for the assessment files, and collecting core for the Drill Core Library.

MINING ACTIVITIES

METALLIC MINERALS

The two major base metal producers in the North Central Region are the Noranda Incorporated (GECO Division) copper-zinc-silver mine at Manitouwadge (7) and the Inco Limited nickel-copper mine at Shebandowan (4). The GECO Mine in 1984 milled 1 382 000 tons of ore to produce 23 030 tons of copper, 36 440 tons of zinc, 380 tons of lead, and 1 404 000 ounces

of silver (Canadian Mines Handbook 1985-86). The Shebandowan Mine has been in continuous production for all of 1985.

The Teck Corporation custom mill (formerly the Pancontinental Mining (Canada) Limited custom mill) in Beardmore closed down in 1985.

The Northern Concentrators Limited's custom mill in Thunder Bay processed 272 tons of ore (B. Doucet, Mill Manager, Northern Concentrators, personal communication, 1985).

Three new gold mines started producing in the Hemlo area (*see* Hemlo Section, this report). Q.C. Explorations Limited has a porta-mill in Thunder Bay to process dredged dump material from the former Silver Islet Mine. Atlantic Mining Corporation set up a vortex mill on the old Sand River Mine property near Beardmore.

INDUSTRIAL MINERALS

Most of the amethyst production came from operations in MacTavish Township, northeast of Thunder Bay. These include the deposits of Gunnard Noyes (3), The Ontario Gem Company (9), J. Barrett Mine (1), The Dorion Amethyst Mine (2), and the Thunder Bay Amethyst Panorama (11).

Recently, Great Lakes Ceramics Incorporated acquired the closed brick plant of Thunderbrick Limited in Rosslyn Village. High alumina clay deposits from Saskatchewan will be used as the raw material for the plant. Twenty-three people will be employed and will initially produce 3 million square feet of ceramic tile a year (Lakehead Living, July 23, 1985, p.1). Tiles produced are slated for eastern Canadian and northeastern U.S. markets.

CLAIM STAKING AND EXPLORATION ACTIVITY

The total number of claims staked in the North Central Region in 1985 was less than the number of claims staked in 1984. The total number of active claims also decreased from the record high in 1984.

The amount of assessment work filed in 1985 was less than that filed in 1984.

SILVER VEINS IN THE THUNDER BAY AREA

INTRODUCTION

Much of the silver mining in the Thunder Bay area took place during a 50-year period, from 1840 to 1890, when the region was isolated and underdeveloped. Records of this mining activity are sketchy and poorly documented. As a result, K.G. Kenwick, Regional Mineral Resources Co-ordinator, initiated a Historical Research Program involving a literature search of available newspapers and journals published during this period. This research has turned up a number of undocumented silver occurrences and extensive data on known mines. A number of these mines were visited under a Section 38 Program (Hazard Lands Survey to locate abandoned mine workings) and by the Resident Geologist's staff during the field season to document the geology.

Recent industry activity is limited to Q.C. Explorations Limited's recovery operation of the dump material at Silver Islet and to E. Johnson's exploration of dumps in the Porcupine Mine area, southwest of Thunder Bay.

REGIONAL GEOLOGY

The rocks of the Thunder Bay area are Precambrian in age. The Archean rocks consist of folded mafic metavolcanics and metasediments intruded by quartz-monzonites which all belong to the Shebandowan "Greenstone Belt". Unconformably deposited on the Archean basement are a series of nearly flat-lying sedimentary rocks of the Gunflint Formation (2000 Ma; Floran and Papike 1975), Rove Formation (1850 Ma; Goldich 1972) and Sibley Group rocks (1300 Ma; Wanless and Loveridge 1976). These rocks have all been intruded by Logan diabase sills. Osler Group sedimentary and volcanic rocks are unconformably deposited on the above Proterozoic rocks. The Osler Group is intruded by Duluth-type gabbros and quartz-feldspar porphyry bodies.

Franklin (1981) divided the silver veins into two main groups: 1) an inland set associated with Logan-age sills, and 2) an island set associated with a Duluth-type gabbro dike. It appears that the Island Group of veins may change into Dorion lead-zinc veins and amethyst veins farther to the east. The general form, mineralogy, and associations of the Mainland and Island Groups are similar.

RECENT RESEARCH

Franklin (1970) carried out a metallogenetic study of the Proterozoic rocks of the Thunder Bay District. Since then, S. Kissin has supervised a number of silver-related B.Sc. theses at Lakehead University: Mosley (1977), Maunula (1979), Smyk (1984), and Harvey (1985). B. Jennings is currently working toward an M.Sc. thesis at Lakehead University studying fluid inclusions in the silver veins of the area.

HISTORY OF SILVER MINING IN THE THUNDER BAY AREA

The following is summarized from Henderson (1981), Mohide (1985), Strickland (1979), French (1976), and the Resident Geologist's Files, Ontario Ministry of Northern Development and Mines, Thunder Bay. Reconnaissance mapping by Logan of the Geological Survey of Canada in 1940, identified a number of mineral occurrences. The first recorded production of copper and silver in the region was from the Prince Location, 15 km southwest of Thunder Bay, in 1846, by the Montreal Mining Company. Most exploration during this period was directed at copper and lead, since gold and silver remained the property of the Crown under mining laws of the period. During 1846 and 1847, the Montreal Mining Company obtained 18 tracks of land, each containing 6000 acres, along the north shore of Lake Superior. In 1864, the mining law was changed allowing silver production but imposing a 10% royalty. In the same year, Peter McKellar

discovered the Thunder Bay Silver Mine near the present day site of the Terry Fox Lookout, just east of Thunder Bay. P. McKellar petitioned the Provincial Government to change the Royalty Law, replacing it with an acreage tax. This change forced the Montreal Mining Company into exploring its vast holdings. In 1868, G. Brown of the Montreal Mining Company discovered silver on a small island in Lake Superior. The property was sold to the Silver Islet Mining Company. After overcoming severe engineering problems, production commenced and continued until 1883.

During this period (1870 to 1880), a number of mines and properties were developed in the area. Among these are the Shuniah Mine, Rabbit Mountain Mine, Porcupine Mine, Badger Mine, East End Silver Mountain Mine, and the West End Silver Mountain Mine. In the 1890s, the price of silver declined sharply from 104.6 in 1890 to 58.26 in 1898 (in current U.S. cents, Mohide 1985) causing all of the mines to close down. A number of attempts were made to reopen the mines but these failed. The total production figures are very sketchy, but it is estimated at 4.7 million ounces of silver (Sergiades 1968).

GENERAL OBSERVATIONS ON SILVER VEINS IN THE THUNDER BAY AREA

1. As noted by Franklin (1981), most of the silver came from veins hosted by the Rove Formation. The relationship appears to be even more restricted. The Rove Formation has three major units: 1) Black pyritic shale and argillite; 2) interbedded argillite and greywacke; and 3) quartzitic greywacke. All major silver producing veins are associated with the black pyritic shale and argillite unit. According to Franklin (1981), this unit of the Rove Formation is metal rich and graphitic. Non-producing carbonate-quartz veins, mineralogically similar to producing veins, cut all rock types in the area including Osler Group volcanic rocks, porphyry intrusions, and Duluth-type gabbro intrusions.
2. The producing silver veins are located within 30 m of diabase dikes or sills. The host Rove Formation rarely exceeds 100 m in thickness, and therefore is in close proximity to the sills and crosscutting dikes. The clearest relationship between the producing part of the vein and a dike is found at the Silver Islet Mine. Production was closely confined to the vein as it cuts the dike.
3. The veins occupy fault structures which commonly show offsets of 50 m or more between diabase sills and sediments. The veins are usually composite. In the Silver Mountain area, early carbonate veins are brecciated and refilled by fluorite, quartz, and sulphide mineralization. In some cases, these veins may be rebrecciated and filled by a barite-dominated vein filling.
4. On a number of properties in the Silver Mountain Area, mineralization occurs at or near the intersection of two vertical dipping veins striking 60° and 90°.
5. The mineralogy of the veins is generally simple, consisting of acanthite, native silver, galena, sphalerite, chalcopyrite (typically altered to chalcocite and malachite), pyrite, barite, fluorite, calcite, and quartz. Acanthite often forms a thin film on fractures in the vein or wall rock and dendritic pods after native silver. Native silver is commonly associated with dark brown sphalerite and purple fluorite. In non-silver bearing sections of the vein, the fluorite is typically green and the sphalerite is honey yellow in colour.

   The veins are vuggy and consist of coarse carbonate, white to pale amethystine quartz, green colliform fluorite, and coarse bladed barite. Galena commonly occurs as skeletal crystals. Cobalt-nickel arsenides have been reported at Silver Islet, Edward Island, and the 3A Mine. Graphite is present at the Silver Islet and Edward Island locations.

PROPERTY DESCRIPTIONS

PORCUPINE MINE

The Porcupine, also known as the Twin City Mine or Creswell Property, is located in the northeastern corner of Gillies Township, in the central part of patented mining claim 96T. The mine is accessed by a series of four adits and two shafts. Production, combined with that of the neighbouring Badger Mine, was 600 000 ounces silver. An attempt to reactivate the mine in the late 1960s failed. In a consultant's report, a small block of ore 20 feet by 20 feet by 3 feet (6.1 m by 6.1 m by 0.9 m) averaging 394.5 ounces silver per ton, or a total of 40 000 ounces silver, was outlined (Resident Geologist's Files, Ontario Ministry of Northern Development and Mines, Thunder Bay).

The silver-bearing vein strikes 60° and dips 90°. The vein is hosted by diabase and Rove Formation shale and occupies a fault that has offset the Rove-diabase contact by 10 m. The vein is 3 m wide below the diabase and 30 cm wide in the diabase. Franklin (1970) cited slickensides in the vein carbonate as evidence for post vein formation movement. Mineralized samples collected in the 1960s (Resident Geologist's Files, Ontario Ministry of Northern Development and Mines, Thunder Bay) consist of coarse white calcite (individual crystals are up to 10 cm) with vuggy sections containing smokey to amethystine quartz. Fragments of Rove formation shale are often rimmed by a thin rind of white quartz and colloform green to purple fluorite. The most common sulphide mineralization is dark brown to honey yellow sphalerite. Acanthite occurs as a coating on fractures and cleavage planes in the calcite and more rarely as crystals on quartz crystals. Native silver occurs along fractures and as dendritic masses. Other sulphide mineralization present includes galena, chalcopyrite, and pyrite.

KEYSTONE MINE

The Keystone or Climax Mine is located in the central part of surveyed mining claim 145T, O'Connor Township. The property is underlain by Rove Formation shales and diabase. At least three veins have been exposed by a series of trenches and shafts. The number six vein is exposed in an open cut, 1 to 3 m deep, 2 m wide, and 50 m long. There are at least two generations of parallel veins. The main vein is 50

to 150 cm wide and consists of coarse carbonate, green fluorite, white quartz, sphalerite, galena, and minor pyrite. Acanthite was observed in dump material. A set of vuggy amethystine quartz veins 3 to 10 cm wide parallel the main vein on the south side. The main vein is bounded by diabase on the north side and Rove Formation shale on the south. An attempt was made by E. Johnson of Thunder Bay in 1985, to re-evaluate a number of muck piles on the property. Several dumps were bulldozed open and a number of two-ton bags of high grade material were collected. The samples consisted of quartz-carbonate with green to purple fluorite, honey yellow to black sphalerite, pyrite, native silver, and acanthite. Samples containing acanthite ran over 50 ounces per ton while those with native silver ran over 100 ounces per ton.

SILVER MOUNTAIN AREA

The Silver Mountain area consists of two properties, the East End and West End Silver Mountain Mines. These properties are located on lots 10, 11, 12, concession II, in Lybster Township, approximately 56 km southwest of Thunder Bay. In 1903, it was estimated that West End and East End Silver Mountain Mines had produced $450 000 and $50 000 worth of silver, respectively (Resident Geologist's Files, Ontario Ministry of Northern Development and Mines, Thunder Bay). A large vein, ranging from 1 to 10 m in width (with an average of 2 m), has been traced for 500 m across the two former producers. The vein occupies a fault at the contact between diabase to the north and Rove Formation shales to the south. Stoping was confined to 15 m of the shale-diabase contact. Production was associated with a series of calcite stringers on the north side of the vein (Resident Geologist's Files, Ontario Ministry of Northern Development and Mines, Thunder Bay).

At the number one shaft, caving exposes the main carbonate vein cutting two smaller vein sets; a barren quartz-carbonate set strikes at 100° and dips 90° and a sulphide-rich vein 20 cm wide strikes at 50° and dips 90°. The stope is developed where the veins intersect.

At the number two shaft, a stope has collapsed exposing unmined parts of the main vein. From north to south, the main vein consists of 15 cm of coarse bladed barite, 30 cm of coarse white calcite, 60 cm of layered quartz-carbonate, 90 cm that has been mined out, andor more. Of these 13, to more than four ounces and of the latter 9, go more than five ounces. 7 contain more than six ounces while two go over 20 ounces and none go over 32 ounces. The average assay for all 425 samples is 0.85 ounces.

Diamond drilling in 1947 to 1955 indicated 60 000 tons of 5.0 ounces per ton silver and 12% fluorite (Mineral Bulletin MR198, Energy Mines and Resources Canada, 1983).

ST. IGNACE ISLAND COPPER-SILVER OCCURRENCE

The St. Ignace Island Occurrence, also called the Harrison Location or Horlac Mines Limited property, is located just north of Finch Point on the northeastern corner of St. Ignace Island in Lake Superior. Two parallel veins, 10 to 20 cm in width, hosted by Osler Group volcanic rocks are exposed in a series of trenches and pits. The Silver Islet Mining Company did the initial work on the property during the 1860s (Resident Geologist's Files, Ontario Ministry of Northern Development and Mines, Thunder Bay). Drilling by Horlac Mines Limited in 1955 encountered quartz-carbonate veins containing chalcocite and native silver. The vertical dipping veins strike 90° but unlike other similar occurrences, there appear to be no associated diabase dikes or sills.

CURRENT RIVER AGATE OCCURRENCE

The property is located in Mining Location 8, MacGregor Township, just west of the Spruce River Road and north of Highway 17.

The area was mapped by the Ontario Geological Survey in 1951 by Moorhouse (1960, Map No. 1960o), and is underlain by Gunflint Formation (carbonates and cherts) and Rove Formation (shales) which have been intruded by Logan diabase sills. Moorhouse (1960) showed a fault trending 65° that forms a contact between the sediments and diabase.

On the property, a diabase sill forms the cap to a steep-sided hill which trends at 65° from the Terry Fox monument to the Spruce River Road. The agate occurs at the base of the hill within Rove Formation shales and Gunflint Formation carbonates.

The agate forms in stalactitic masses 4 to 8 cm across by 30 cm long in a fine-grained chalky matrix. The colour varies from white to pale orange to grey. The coloured bands form a circular pattern, with individual layers ranging from 1 to 3 mm in width.

The exposed area of agate is 6 m by 9 m with agate forming a conformable layer (50% to 70% agate up to 1 m thick). Agate floats could be observed up to 100 m east of this exposure in talus. Minor pyrite and black fine-grained sulphide mineralization occurs in the agate.

This occurrence appears to be the strike extension of the Current River agate exposed in the first outcrop east of the Terry Fox Lookout. Here, small lenses of agate (20 cm by 10 cm) and sulphide mineralization occur in the upper fragmental carbonate unit of the Gunflint Formation near the contact with the Rove Formation shales.

The agate may have been formed from solutions, heated by diabase, encountering the carbonates.

Samples of agate cut by B. Haywood, Thunder Bay Lapidary Club, take a high polish. Mounted samples are attractive and should be easily marketed. The generally quality and nature of the agate is similar to "Mexican Lace Agate" or "Crazy Lace Agate".

HEMLO AREA

Currently, three companies, Noranda Incorporated, Teck Corporation, and Lac Minerals Limited, have brought their Hemlo properties into production. Noranda Incorporated initiated production in March of 1985 at the rate of 750 tonnes per day. Production is estimated at 92 000 ounces gold for 1985 (The Northern Miner, December 9, 1985). Teck Corporation's

Teck-Corona Mine officially opened in September 1985. The mill, rated at 1000 tonnes per day, was expected to produce 54 075 ounces gold in 1985 (The Northern Miner, September 16, 1985). Lac Minerals Limited began producing from their open pit on October 21, 1985 (The Northern Miner, October 28, 1985).

Exploration activity in the Hemlo area, from Marathon to White River, has remained very high. The majority of companies have filed sufficient assessment work to hold ground for a number of years.

Geological Data Inventory Folios (GDIFs) have been prepared for the area. The general geology of the main Hemlo deposit has been summarized in a field trip guidebook (Patterson 1984).

LYTTON MINERALS LIMITED PROPERTY

(including the former Bowhill Gold Mines Property and the Heron Bay Gold Mine Property also called Peekongay Property)

The property, located in Pic Township, is centred around the town of Heron Bay, and stretches from Lake Superior to the Pic River.

The area is underlain by felsic metavolcanics (breccia to tuffs) and mafic metavolcanics which have been intruded by granitic rocks, diabase dikes, and lamprophyre dikes. The felsic metavolcanics are a part of the Heron Bay series (Muir 1982).

A large scale M-shaped fold, approximately 2 km across, occurs to the south of the Lytton property and is defined by folded foliation (visible on 1 inch to 1/2 mile airphotos). A strong east-west lineament occurs just to the north of the town of Heron Bay.

Hartwick *et al.* (1985) described the geology of the property as follows:

> The volcanic succession, which underlies the Peekongay Property, forms part of the Heron Bay Group and is approximately 2 miles (3.2 km) thick on the property. These rocks can be subdivided into three major sequences:
>
> (1) A northern sequence of mafic to intermediate, locally pillowed flows and lesser pyroclastic rocks approximately 3,600 feet (1,100 m) thick. A significant proportion of the mafic to intermediate flows are pervasively silicified giving the outcrops a more "felsic" appearance.
>
> (2) A central zone about 2,000 feet (600 m) thick comprising a complex succession of interbedded fine to coarse-grained pyroclastics of intermediate composition with local interbedded volcaniclastic horizons. The "C" Zone occurs near the southern edge of the central zone.
>
> (3) A southern sequence of coarse, felsic to intermediate pyroclastics about 5,000 feet (1,500 m) thick. A trend to a more felsic composition, as well as a general coarsening of clast size, appears to occur southwards.

As summarized from Hartwick *et al.* (1985), four major environments of gold mineralization occur on the property:

1. Pyritic quartz-rich molybdenite-bearing possibly stratiform unit in mafic to intermediate tuffs ("C" Zone).
2. Vuggy, pyritic quartz-carbonate veins and stringers cutting a possible subvolcanic quartz-feldspar porphyry sill ("Porphyry" Zone).
3. Pyritic, silicified, and quartz-sericite altered, dacitic pyroclastic rocks and, to a lesser extent, mafic to intermediate tuffs (Main Zone, eastern part of North Zone).
4. Quartz-carbonate veins and vein breccias with variable amounts of pyrite, chalcopyrite, galena, sphalerite, and tourmaline (Bowhill trench, 1872 shaft area trench, western part of North Zone).

Ore grade intersections over significant widths (i.e. 6 feet (2 m) or greater) have been obtained from the "C" and "Porphyry" Zones. In contrast, the silicified and quartz-sericite altered pyroclastic rocks, of which the Main Zone is the most prominent, are characterized by geochemically anomalous gold values in the order of 100 to 200 ppb with local highs up to 0.11 ounce gold per ton over 3.1 feet (0.95 m), but no ore grade intersections have been obtained (Hartwick *et al.* 1985).

Quartz-carbonate veins and vein breccia occur in essentially all lithologies and, although there are several occurrences of these veins which carry gold values >0.40 ounce gold per ton, they are very erratic and discontinuous. The lateral and vertical continuity of the high grade intersections is very limited.

Porphyry Zone

Further detailed work by Derry, Michener, Booth and Wahl identified a mylonite zone on the north side of a porphyry intrusion 1 km west of Heron Bay. This unit was previously called a thinly bedded hematitic ash tuff marker (B. Pearson, Geological Consultant, Derry, Michener, Booth and Wahl, Toronto, personal communication, 1985).

The unit is highly foliated and locally folded. It is comprised of fine-grained, red (hematitic) thinly laminated chlorite and felsic layers. In drill core, the mylonite grades southward into a sheared and deformed feldspar porphyry. The porphyry contains 10% white quartz veins from 1 to 5 cm wide with minor pyrite and 3% to 5% black tourmaline. A value of 0.19 ounce gold per ton across 23.5 feet has been intersected within the porphyry, near the hanging wall (Resident Geologist's Files, Ontario Ministry of Northern Development and Mines, Thunder Bay).

C-Zone Mineralization

The C-Zone mineralization occurs at or near the footwall of the feldspar porphyry. Mineralization consists of layers and lenses of quartz up to 1 cm thick in a chlorite schist (possibly a sheared mafic metavolcanic). The quartz-rich layers contain molybdenite. Pyrite (50% to 10%) occurs as 1 to 3 mm cubes which have been deformed and possibly rotated in foliation. The zone appears to crosscut the mafic metavolcanics and the feldspar porphyry. Late quartz-carbonate veins cut the foliation in the zone. Most of the rocks north of the railway tracks consist of heavily carbonated mafic metavolcanics which

have a felsic appearance. The best diamond drill intersection obtained was 17.0 feet of 0.19 ounce gold per ton (Resident Geologist's Files, Ontario Ministry of Northern Development and Mines, Thunder Bay).

Main Zone Mineralization

The zone consists of a series of sericite schist units within felsic metavolcanics that trend at 60° across the property. In the moderately foliated sericite schist, 5% to 10% blue quartz-eyes, and up to 2 mm in size, occur. The quartz-eyes are deformed parallel to foliation. In the most strongly foliated sections, quartz-eyes are absent and the narrow quartz-rich layers (<2 mm) contain molybdenite. Drilling and surface exploration has defined five parallel units. A number of occurrences are known on the zone. The best intersection reported was 4.83 ounces gold per ton across 1.0 foot (Resident Geologist's Files, Ontario Ministry of Northern Development and Mines, Thunder Bay).

a) Bowhill Mines Trench: Described by Hartwick *et al.* (1985), this trench is a section of the Main Zone (located about 1 km west of Heron Bay):

> This trench, excavated by Bowhill Mines in the middle 1930's, is about 200 feet (60 m) long by 30 feet (9 m) deep and 10 feet (3 m) wide. The trench is largely caved in but the pyritic quartz-sericite schist unit is exposed at the end of the carbonate-quartz vein which contains sphalerite, galena and pyrite; a bulk sample of 500 lbs; taken presumably from this vein material by Bowhill Mines, assayed 0.3 oz Au/ton and 1.5 oz Ag/ton.

Drilling and geochemical work by Lytton Minerals Limited (Resident Geologist's Files, Ontario Ministry of Northern Development and Mines, Thunder Bay) shows the Main Zone to be Na depleted and K, Mo, Au, Zn, Cu enriched. The Main Zone and the carbonate vein are cut by a lamprophyre dike. The carbonate veins contains black tourmaline and molybdenite.

Stripping on the main zone west of the Bowhill Mines occurrence (1100 m west of Highway 627 and the Canadian Pacific Railway) exposes a shear zone which shows evidence of progressive deformation. The earliest phase, largely ductile, during which volcanic fragments within a felsic pyroclastic were being folded and stretched parallel to foliation, was followed by an event in which discrete sericite schist zones, 20 to 100 cm wide and heavily carbonated, cut across the ductile shear. Carbonate pods within the sericite schist are deformed. During this event, a mafic dike, 30 to 60 cm wide, containing fragments of sericite schist, intruded into the sericite schist. This dike is folded as it crosses the sericitic schist zone. The final phase appears to have been brittle deformation, with the formation of quartz-tourmaline veins along the margin of the mafic dike and in the carbonate pods.

b) Heron Bay Gold Mine: Hartwick *et al.* (1985) described the property as follows:

> This last outcrop stop is the site of the early workings described by Bell. Two shafts are present, one shallow shaft, probably about 8 m deep in the eastern part of the trenched area, and the second shaft, which is about 16 m deep, in the central part of the trenched area. These two shafts are about 40 m apart. Within this trench you will see that the main target has been a carbonate-quartz vein which strikes west-northwesterly. This vein occurs along a fault which cuts the volcanic stratigraphy. The quartz vein carries sporadic gold values; the best result from our sampling is 0.314 oz Au/ton over 0.9 m. The pyritic quartz-sericite unit is located about 25 m south of the trench but is not exposed.

The vein carries black tourmaline, molybdenite, galena, pyrite, and minor chalcopyrite. Barite has been identified by X-ray diffraction (Geoscience Laboratories, Ontario Geological Survey, Toronto). The felsic metavolcanics are foliated at 65°, dipping 50°N and the fragments are lineated at 45°W. The veins strike 95°, dip vertically, and crosscut the metamorphic foliation.

South Zone: A sericitic zone, similar to the main zone occurs approximately 100 m south of the Heron Bay Gold Mine. Stripping and trenching has exposed quartz-carbonate veins within a sheared volcanic breccia. The veins contain chalcopyrite, galena, pyrite, and tourmaline.

QUED RESOURCES CORPORATION

The property is located approximately 48 km northeast of Marathon and 3 km north of Solong Lake.

Siragusa (1984) mapped the area for the Ontario Geological Survey. The property is underlain predominantly by mafic metavolcanics, commonly pillowed with south-facing tops. A narrow unit of felsic metavolcanics is exposed in the southwestern part of the property. The regional trend of the units is 125°, dipping 70°S.

Geochemistry (Au, Zn, Cu) and IP have outlined three anomalous zones trending at 125° across the property. These zones were tested by trenching and diamond drilling. The pattern of trenching consists of a "Main" north-south trench (QTIA), 70 m by 800 m long through claims TB774250 and TB774251 and a series of smaller trenches made along the strike of the anomalous zones on claims TB774249 and TB774255.

Zone A

Zone A occurs in the main trench near the contact between a quartz-feldspar porphyry and mafic metavolcanics. The feldspar phenocrysts in the porphyry have been deformed, and the porphyry has been altered to a sericite schist. The mafic metavolcanics are chlorite schists with pyrite phenocrysts up to 3 mm (10% of the unit). The porphyry contains inclusions of mafic metavolcanics and appears to be intrusive.

Zone B

In the main trench (approximately the centre of claim TB774251), a series of quartz veins occur in a chlorite schist. Pyrite occurs as porphyroblasts up to 2 mm in size adjacent to the vein and 10 cm into the schist.

Zone C

A highly deformed zone of chert-pyrite-magnetite ironstone is located at the north end of the main trench and in several of the smaller trenches. The ironstone has been intruded by feldspar porphyries (now deformed and silicified). The associated mafic metavolcanics are south facing (pillows stretched 2:1) and appear less deformed. Values of up to 0.081 ounce gold per ton across 5 m have been reported for the zone (QUED News Release, February 27, 1984). Drilling encountered a number of anomalous zones (100 ppb), the highest of which returned 1785 ppb gold across one metre.

In trench QT3, approximately 100 m west of the north end of the main trench, visible gold was noted in a folded quartz vein hosted in mafic metavolcanics (J. Dumouchel, Geologist, Ore Quest Limited, Vancouver, personal communication, 1985).

CHAVIN OF CANADA LIMITED

The property is located approximately 40 km northeast of Marathon, between Dead Otter Lake and Highway 614. The area was mapped by Siragusa (1984) for the Ontario Geological Survey. The eastern part of the property is underlain by mafic metavolcanics which have been intruded by a granitic body centred on Dotted Lake. The granitic rocks on the shore of Dotted Lake, near the end of the access road, consist of 20% quartz, 40% plagioclase, 25% potassium feldspar, and 20% biotite. They are medium grained, well foliated (striking 170° and dipping 70°W), and are cut by numerous quartz veins.

The geology of the property is exposed in two trenches:

1. Approximately 100 m west of Dotted Lake, south of the access road, a trench, 10 m by 20 m by 1 m, exposes a shear zone (amphibole schist) cutting amphibolites (mafic metavolcanics). The amphibole schist is up to 1 m wide, fine grained, well foliated (striking 110° and dipping 90°) with chlorite-rich layers containing up to 2% pyrrhotite. A white, glassy quartz vein, 20 to 30 cm wide occurs parallel to foliation within the amphibole schist. Only minor pyrrhotite was noted in the quartz vein. The amphibolite host rock is green in colour, weakly foliated (striking 160° and dipping 70°W) and consists of 60% amphibole and 40% plagioclase and minor epidote pods. Assays of the quartz vein and the amphibolite schist returned <0.01 ounce gold per ton (Geoscience Laboratories, Ontario Geological Survey, Toronto).
2. 400 m west of Dotted Lake on the south side of the access road, a trench and stripped area, 900 m by 10 m by 5 m, exposes a shear zone (amphibole-chlorite schist) up to 4 m wide cutting pillowed mafic metavolcanics. The schist contains a number of sugary white quartz veins ranging from 30 to 100 cm in width, which have been partly deformed. The veins contain pyrite, molybdenite, chalcopyrite, and chloritic pods. The vein and the schist trend at 160°, dipping 70°W. A number of narrow (10 cm) feldspar porphyry dikes intrude the amphibole schist parallel to foliation. The host rock is a pillowed mafic metavolcanic in which the pillows are stretched 2:1. Alteration of the pillows has produced dark rims, 20 to 40 cm in width, and a bleached core. A Logan type diabase dike, 2 m wide, and trending north-south cuts the amphibole schist 20 m south of the road. Assays of up to 3000 ppb gold and 1000 ppm Mo have been reported (Resident Geologist's Files, Ontario Ministry of Northern Development and Mines, Thunder Bay).

OTHER PROPERTIES

1. The Bel Air Resources Property is located 4 km west of the Teck-Corona Hemlo Mine. Westfield Minerals Limited has carried out a program of geological mapping, geophysics, geochemistry, trenching, and drilling. The general stratigraphy from north to south (based on Westfield Minerals Limited data), consists of felsic metasediments (including a westward extension of the "Highway Zone" of Golden Sceptre), mafic metavolcanics, the Hemlo Fault Zone, metasediments (calc-silicates, siltstone, and pelites), volcanoclastics, and metasediments. Trenching has exposed pyritic sericite schists with green mica. The Hemlo Fault appears to gently crosscut the stratigraphy, and is terminated at the Rous Lake Pluton.
2. The Knut Kuhner Showing is located 1 km south of Page Lake, 10 km northeast of the Marathon airport on the property of Gowganda Resources Incorporated. The main showing was stripped and trenched by Kerr Addison Mines Limited in 1970. The occurrence consists of felsic metavolcanics, chert, and graphitic schists. Sulphide-rich units, containing pyrite and pyrrhotite, are associated with the chert. Assays of grab samples returned up to 3450 ppb gold and 0.73% zinc (Geoscience Laboratories, Ontario Geological Survey, Toronto).
3. Esso Resources Canada Limited reported the results of drilling on their ground east of Heron Bay. The property is apparently on strike with Lytton Resources' Main Zone. Hole No. 1 encountered an intermediate to feldspathic crystal tuff and lapilli-tuff containing contorted foliation and brecciated quartz veins, with pink calcite, pyrite, and molybdenite. Assays by Esso Resources Canada Limited returned up to 1300 ppb gold and 280 ppm molybdenum across 0.6 m (Resident Geologist's Files, Ontario Ministry of Northern Development and Mines, Thunder Bay).
4. The Hardy International Development property is located approximately 3 km east of the Esso Resources Canada Limited property. Drilling by Teck Exploration Limited encountered a hematitic intermediate schist, containing a trace of molybdenite similar to Lytton's "Hematitic Ash Tuff" or mylonite (Resident Geologist's Files, Ontario Min-

istry of Northern Development and Mines, Thunder Bay).

5. Gold Fields Mining Corporation carried out cross-sectional drilling on the International Laco Resources Limited and Triple Crown Resources Limited properties (west of the Golden Sceptre property). Drilling encountered extensive units of ultramafic metavolcanics, containing spinifex textures, previously unknown in the stratigraphy of the belt.
6. Drilling on the Interlake Development Corporation property by Noranda Exploration Company Limited encountered a number of mineralized zones including the possible down dip extension of the Lac Minerals Limited C-Zone. Hole 1L-2-XW returned 136 feet of 0.05 ounce gold per ton (The Northern Miner, July 11, 1985). Hole 1L-2X returned 24.7 feet of 0.186 ounce gold per ton (George Cross News Letter, No. 90, 1985).
7. Fleck Resources Limited has purchased the Anaconda Canada Exploration Limited property 8 km northeast of Marathon. The initial work in the 1960s by Anaconda Canada Exploration Limited outlined 34.4 million tons averaging 0.039 ounce platinum/palladium per ton and 0.47% copper (1985 Fleck Resources Limited Annual Report) hosted in a gabbro on the eastern margin of the Coldwell Complex. Fleck Resources Limited carried out a program involving the re-assaying of the core, stripping, trenching, geological mapping, and diamond drilling.

BEARDMORE–GERALDTON ECONOMIC GEOLOGIST PROGRAM by J.K. Mason and G.D. White

INTRODUCTION

The Beardmore-Geraldton Economic Geologist Program is funded by the Ontario Ministry of Northern Development and Mines. The program was staffed by John Mason and by Gerry White until November 1985. The objective of the program is to stimulate exploration activity in the Beardmore-Geraldton area by assisting prospectors and mining activities with property visits, sampling, mapping, literature searches, field trips, documentation of all occurrences, and interpretation of various geological environments.

PRODUCING GOLD MINES AND MAJOR EXPLORATION PROGRAMS

Teck Corporation (Leitch Division) milled approximately 45 000 tons of screened dump material, from the Leitch Gold Mine, at the former Pan-Continental Mining (Canada) Limited Mill (1984-85) (R. Dunning, Project Superintendent, Teck Corporation (Leitch Division), Beardmore, personal communication, 1985). The mill closed temporarily on January 31, 1985. Northern Concentrators milled 200 tons of ore from the Crooked Green Creek #1 zone in Pifher Township.

Phoenix Gold Mines Limited continued with year two of a multi-phase exploration program on the Quebec-Sturgeon River Gold Mine property, located in Irwin, Pifher, Walters, and Elmhirst Townships. Geological mapping, overburden geochemistry, stripping, trenching, channel sampling, and bulk sampling were conducted on ground lying east and north of the main underground development.

Muscocho Explorations Limited initiated a major exploration program on the Tashota-Nipigon Mine property in the Onaman Lake area. Approximately 4500 m of diamond drilling was supplemented by extensive stripping.

Atlantic Mining Corporation conducted exploration programs at two locations. At the Sand River Mine site, an experimental mill, termed the Dunbar Pulverizer 3M9, was installed to concentrate gold-bearing vein quartz from the "Sand River Vein" and the waste dump. The mill uses compressed air to collide jaw crushed 1/4 inch quartz fragments. Stripping, trenching, channel sampling, air magnetometer and air E.M. surveys were conducted on the Twin Falls property in Irwin-Pifher Townships.

Metalore Resources Limited continued diamond drilling the Brookbank Prospect and western parts of their extensive claim holdings in Irwin Township.

Canamax Resources Incorporated diamond drilled a part of the Paulpic Prospect in the Tashota area. The tonnage and grade estimate prior to the 1985 drill program was 200 000 tonnes averaging 0.23 ounce gold per ton (Canadian Mines Handbook, 1984-85). Canamax Resources Incorporated also diamond drilled the Watson Lake (Theriault-Rentz Option) Occurrences, an eastern extension of the favourable Leitch Gold Mines iron formation horizon. A summary of the exploration program is outlined in Table 4.4.

GENERAL GEOLOGY AND STRUCTURE

The Beardmore-Geraldton area has been divided into two belts. The Beardmore-Geraldton Belt and the Onaman-Tashota Metavolcanic Belt are separated by the Paint Lake Fault, a major transcurrent fault.

A detailed description of the geology and gold mineralization of the Beardmore-Geraldton Belt is provided in Mason and McConnell (1983) and by Mason and White *in* Patterson *et al.* (1984, 1985).

GEOLOGY OF THE ONAMAN-TASHOTA METAVOLCANIC BELT

The Onaman-Tashota Metavolcanic Belt, a part of the Wabigoon Subprovince, is described by Mason and White *in* Patterson *et al.* (1984).

GOLD MINERALIZATION

Gold is hosted in two environments within the Onaman-Tashota Belt:

1. Vein Shear Zone Type. Gold is associated with quartz (carbonate) veins and shear zones hosted in metavolcanics, often marginal to felsic intrusions, e.g. Tashota-Nipigon Mine, Brenbar Mine, Quebec-Sturgeon Mine, Peddle Lake Occurrence (Phoenix Vein), Twin Falls Occurrence.
2. Chemical Metasediment Type. Gold is hosted by chemical metasediments (chert, iron formation), e.g. Paulpic Prospect and Deeds Lake (New Gol-

30. West Side Long Lac Occurrence (Quaternary Mining and Exploration Company Ltd.)

dvue Mines) Occurrence hosted in metavolcanics.

Tashota-Nipigon Mine

The Tashota-Nipigon Mine is located immediately northwest of Onaman Lake and south of Oboshkegan Township. The original discovery was made by J. McKechnie in 1923 on claim KK524 and mining development commenced in 1928. From 1935 to 1938, production totaled 12 355.7 ounces of gold, 14 527 ounces of silver, and 360 306 pounds of copper (Mineral Resources Branch, Department of Energy, Mines and Resources, Ottawa). Tashota-Nipigon Mines and International Mine Services Limited undertook exploration programs after the mine closed. During 1985, Muscocho Explorations Limited initiated a 4570 m (15 000-foot) drill program supplemented by stripping.

The property is underlain by pillowed (variolitic) and massive mafic metavolcanics, termed the "footwall zone" by Muscocho Explorations Limited (H. Matthews, Geologist, Muscocho Explorations Limited, personal communication, 1985). Granodiorite and gabbro appear to have intruded lower in the sequence. The metavolcanics commonly contain 2% chalcopyrite and pyrrhotite. Alteration minerals are biotite and epidote, the latter noticeable in pillow selvages and fractures. Gold mineralization is associated with the central and upper part of the metavolcanics.

Overlying the metavolcanics is a 9 to 25 m thick oxide/sulphide facies iron formation. Chert-chlorite, chlorite-garnet-magnetite, siltstone and magnetite-chert beds occur within the iron formation unit. Pyrite commonly occurs within a matrix of coarser pyrrhotite. Minor chalcopyrite is also present. Regionally, the stratigraphy dips to the north, but in detail it is tightly folded and plunges 55° to 65°NW.

Main mine production has come from the A zone, which outcrops on surface approximately 6 m west of the shaft. The zone, which has been described by Tindale (1967) and Moorhouse (1939), is present as a lenticular sheet-like orebody ranging from 0.5 to 2.0 m thick on the 625 foot (190 m) level and 720 foot (220 m) level, respectively. The zone is composed of highly silicified mafic metavolcanics with foliation parallel quartz veining and associated disseminated pyrrhotite and chalcopyrite. The total sulphide content is typically 2% and alteration minerals present are epidote and biotite. Biotite is closely associated with gold mineralization (H. Matthews, Geologist, Muscocho Explorations Limited, Toronto, personal communication, 1985). Moorhouse (1939) reported that under the A Zone a deep surface "drill hole to 925 feet gave an average value of 0.33 ounces per ton over a true width of 13.1 feet." During 1985, Muscocho Explorations Limited completed several drillholes below the 625 foot (190 m) level and intersected A-type mineralization.

Diamond drilling was also completed on the D and G zones (Zone A through G are present on the property). The D zone may be a faulted extension of the A zone while the G zone is a series of quartz lenses hosting gold and pyrrhotite. The zones are all interpreted to be lenses that approach each other down plunge to the west. The G zone is located approximately 275 m (900 feet) west of the old shaft. The Northern Miner (October 14, 1985) reported the following:

> The two deepest holes on the zone to date were drilled 50 feet apart and both intersected the gold bearing structure at a vertical depth of 285 feet. They returned assays of 0.37 oz gold per ton over 5 feet and 0.26 oz gold per ton over 4.5 feet, respectively.

Elmhirst-Miron Occurrence

In 1985, Bill Miron discovered a new gold occurrence on claim TB81378, located 1 km northwest of Wilkinson Lake, within the northeastern part of Elmhirst Township.

The six-claim property (TB813373 to TB813378) straddles the contact between the Elmhirst Lake Stock, a granodiorite-quartz diorite intrusion, and intermediate to predominantly felsic metavolcanics mainly feldspar porphyry (Mackasey and Wallace 1978). The occurrence is hosted by granodiorite and consists of two parallel shear zones that have been exposed by stripping. The zones strike 333°, dip steeply to the east, and are separated by 30 m of unexposed bedrock. Much of the work to date (stripping and trenching) has been concentrated on the eastern zone (Zone #1) along a 67 m strike length. This zone is typically lenticular, up to 0.3 m in width, and consists of recrystallized quartz breccia material. Mineralization within the zone consists of, up to 10% fine pyrite present as thin discontinuous seams, disseminated coarser 1 to 3 mm euhedral pyrite, and rare patches of chalcopyrite. In addition, pyrite is associated with inclusions of granodiorite. Prominent pink potassic alteration is present and sericite was noted on the shear zone margins. The massive granodiorite host is mineralized and weakly altered for 0.6 m on either side of the breccia zone.

Gold mineralization occurs over a width of 1.5 m and is associated with the pyrite. The breccia zone-massive granodiorite contact is characterized by pyritic sericite hosting some of the better gold values.

Northern Concentrators have completed milling of 41.8 tons bulk sampled from zone #1. Head assays processed by Bondar-Clegg Company Limited averaged 0.325 ounce gold per ton (B. Miron, Prospector, Thunder Bay, personal communication, 1985).

Twin Falls Occurrence

The Twin Falls Occurrence is located in northwestern Irwin Township, 1 km northeast of Twin Falls, Sturgeon River, (Namewaminikan River). The occurrence, situated within a 41 claim group (TB746779) under option to Atlantic Mining Corporation, was discovered in 1985 by vendors J. Ternowesky and P. Skalesky.

The Twin Falls property occurs within the southern part of the Onaman-Tashota Metavolcanic Belt, and locally in a felsic metavolcanic unit which hosts the Quebec-Sturgeon River and Brenbar Mines. The claim group is underlain by a medium- to coarse-grained felsic metavolcanic breccia and feldspar and quartz-feldspar porphyry. The Musca Lake Fault transverses the southern boundary of the claim group

and may have contributed to the intense shearing observed at the Twin Falls Occurrence. Regional foliation ranges from 90° to 110° with a steep southerly dip.

The Twin Falls Occurrence is situated in the extreme southwestern part of the claim group. A major backhoe stripping program has exposed a 60 m by 225 m pyritic zone hosted in highly sheared quartz-eye feldspar-porphyry or felsic tuff. The zone strikes at 102° and dips steeply to the south. Pyrite mineralization (ranging from 1% to 2%) is pervasive throughout the unit, occurring as fine subhedral to euhedral grains. Pyrite also occurs as more massive discontinuous conformable bands up to 5 mm in width and, in a few locations, as massive pyrite in vitreous quartz "veins". Carbonatization, silicification, and sericitization are present on a local and regional scale. It is within these zones of more massive pyrite mineralization that the highest gold assays were obtained. Detailed systematic channel sampling has recently been completed by Atlantic Mining Corporation (November 25, 1985) and results are pending. Grab samples collected by the author have assayed up to 0.74 ounce gold per ton (Geoscience Laboratories, Ontario Geological Survey, Toronto).

Peddle Lake Occurrence

The Peddle Lake Occurrence is situated on the "River Road" in southwestern Pifher Township, on claim TB863167.

The occurrence was discovered in 1974 by Lynx-Canada Explorations Limited and examined as a copper occurrence. An I.P. survey completed during the same year detected an anomaly coincident with the occurrence. During 1985, the Peddle Lake Occurrence was backhoe stripped by P. Lassila, D. Thorsteinson, and N. Cox, holders of the claim.

The regional geology is similar to the Twin Falls Occurrence (*see* previous property description). The properties are underlain by intermediate to felsic metavolcanics of the Onaman-Tashota Metavolcanic Belt and lie 1.2 km apart. The copper occurrence, now known as the South Zone, was of little interest until mid-1985 when the gold potential of the Peddle Lake Occurrence was examined (a north zone has been uncovered, but is poorly exposed to date).

The south zone is a highly sheared feldspar-porphyry up to 2.5 m in width. It contains subhedral phenocrysts of feldspar typically crowded and homogeneous but it can have rare, stretched, lapilli-sized, feldspar porphyry fragments, and therefore, may be classified as an autobreccia. The south zone strikes 112° and dips 78°N. One to three percent chalcopyrite is present, as well as minor amounts of pyrite, bornite, and native copper.

Grab samples collected by the authors assayed up to 0.44 ounce gold per ton and 5.4% copper (Geoscience Laboratories, Ontario Geological Survey, Toronto).

Phoenix Gold Mines Limited

Phoenix Gold Mines Limited continued with year two of an exploration program on the Quebec-Sturgeon River Gold Mine property, 20 km northeast of Beardmore, Ontario. The property is situated at the common corner of Irwin, Walters, Pifher, and Elmhirst Townships on the south side of the Sturgeon River (Namewaminikan River) and consists of 35 leased claims. Between 1936 and 1942, the mine produced 73 438 ounces of gold grading 0.51 ounce gold per ton (Mason and McConnell 1983). During 1985, stripping, trenching, channel sampling, and bulk sampling were conducted on auriferous quartz veins east of the old mine site and Highway #801, and to a limited extent north of the shaft and west of the shaft. Basal till geochemical surveys and detailed geological mapping were continued over much of the entire property.

Mackasey (1975) described the geology over the property:

> The area is underlain by intermediate to felsic metavolcanics that have been intruded by granodiorite, mafic dikes, quartz veins and diabase dikes. The metavolcanics are medium grey to dark green and vary from massive to foliated.

Veining is proximal to the contact between the metavolcanics and the Elmhirst Lake Stock (granodiorite and quartz diorite) to the north and the Coyle Lake Stock (granodiorite) to the east.

Work during the 1984 and 1985 field seasons has located some 15 new veins, additional to the 67 veins previously documented on the property. East of Highway 801, veins A-2, A-4, A-6, A-9, 85-A-2, 85-A-5, and 85-A-6 are the most significant gold targets located to date. (Note: prefix A denotes Aguara property, the east part of the Phoenix Gold Mines Limited property). All veins are hosted by feldspathic and porphyritic rhyolite to dacite and, to a limited extent, by granodiorite or quartz diorite. Lenticular quartz and quartz-carbonate veins are associated with ductile shearing and, more commonly, with simple, single fractures. Local shearing, represented by sericite schist, is displayed at vein contacts. Veins range up to 0.9 m in width and two distinct vein sets have been noted: one striking 45° to 65° (approximate) and the other striking more northerly. The #3 production vein strikes 13°. Silicification is the main form of alteration noted in the felsic metavolcanics.

Two veins discovered in 1985, 85-A-2 and 85-A-5, host good visible gold and a new extension of A-9 also contains visible gold.

The character of the veins is variable. Vein A-2 is 915 m long, strikes 45° and is composed of white quartz containing clots and disseminations of chalcopyrite, pyrite, and native gold. Generally, <2% total sulphides are present. Contrasting with A-2 is vein A-4 which is a cherty brecciated zone of interbanded sphalerite, magnetite, ilmenite, chalcopyrite, quartz and carbonate containing up to 15% total sulphides. Veins A-4 and A-6 strike northerly. A-6 is 60 m long and primarily a vitreous quartz vein containing pyrite, chalcopyrite, and sphalerite. Assays up to 1.235 ounces gold per ton on chip samples across the vein were reported by Phoenix Gold Mines Limited (L. Koskitalo, Project Geologist, Phoenix Gold Mines Limited, Toronto, personal communication 1985).

Veins 85-A-2 and A-9 are crack-seal type veins similar to the #3 production vein, hosting coarse visible gold associated with sericite, chlorite, or carbonate seams. (Crack-seal texture implies parts of the former wall rock were broken away as the quartz vein was generating.)

Vein 85-M-1 is a new gold occurrence located approximately 480 m north of the shaft area on the former Macjoe property, now a part of the Phoenix Gold Mines Limited property. This quartz occurs in altered granodiorite, strikes approximately 15°, and averages 36 to 56 cm (up to 1.2 m) in width. Assay results indicate an average grade of 0.825 ounce gold per ton over an average width of 47.2 cm for a length of 150 m (O.A. Seeber, President, Phoenix Gold Mines Limited, Toronto, personal communication, 1985).

RECOMMENDATIONS FOR EXPLORATION

Exploration for gold is recommended within parts of the Onaman-Tashota Metavolcanic Belt, where the potential for the discovery of medium to large tonnages of gold-bearing disseminated sulphide deposits are present. Areas that contain vein-type gold mineralization should be prospected for disseminated auriferous sulphide (pyrite, pyrrhotite, chalcopyrite) zones, similar to the Peddle Lake and Twin Falls discoveries. Sulphide zones within intermediate to felsic metavolcanics from the Irwin-Pifher-McComber Townships area north to the Marshall-O'Sullivan Lake area should be assayed for gold. Historically, mainly the vein type gold deposits and occurrences have been trenched and mined in the Onaman-Tashota Belt. When gold values are detected in sulphide zones, induced polarization, stripping, and channel sampling, followed by diamond drilling should be used to evaluate such targets.

The area from O'Sullivan Lake to Maun Lake should be re-examined. Copper and arsenopyrite occurrences are frequently associated with gold and silver.

Gold mineralization is associated with metamorphic biotite at the Tashota-Nipigon Mine. Other sulphide occurrences, or biotite schist zones often associated with chloritic metavolcanics, should be assayed for gold.

Extensions of the Bankfield-Tombill Fault within the main Beardmore-Geraldton Belt should be explored for fault generated feldspar porphyries, silicified and pyritic metasediments, and iron formation hosting possible replacement sulphides, all of which may contain auriferous zones. Magnetometer surveys, I.P. surveys, overburden till sampling, and backhoe to bulldozer stripping programs are recommended.

SCHREIBER–TERRACE BAY ECONOMIC GEOLOGIST PROGRAM by B.R. Schnieders and A.A. Speed

INTRODUCTION

In 1985, the Schreiber-Terrace Bay Economic Geologist Program entered its third year of operation. The program was initiated and is funded by the Ontario Ministry of Northern Development and Mines.

B.R. Schnieders and A.A. Speed are responsible for the program and work out of the Resident Geologist Office.

The purpose of the program is three-fold:

1. To provide assistance and information to prospectors and mining companies working in the area.
2. To document old and new mineral occurrences and establish a database.
3. To stimulate mineral exploration and to monitor the exploration activity.

The program covers an area from Nipigon east to Marathon.

During 1985, approximately 35 properties were visited in the program area (Figure 4.5, Table 4.5). All assays reported in the following property descriptions were performed by the Geoscience Laboratories, Ontario Geological Survey, Toronto, unless otherwise noted.

GENERAL GEOLOGY

The general geology of this area is described by B.R. Schnieders and A.A. Speed in Patterson *et al.* 1985.

ECONOMIC GEOLOGY

Exploration for gold and base metals in the Schreiber-Terrace Bay area remained at a high level during 1985, with the staking of more than 90% of the "high potential" ground (metavolcanics and metasediments). The area has been actively explored since the late 1800s. The area's exploration history is summarized in Patterson *et al.* 1985.

GOLD MINERALIZATION

Recent studies on controls of gold mineralization and the role of felsic intrusions in gold mineralization have been performed by Carter (1980a, 1980b), Marmont and Colvine (1981), Marmont (1983, 1984), and Patterson *et al.* 1984). The following subdivision of gold mineralization types incorporates results of the above studies and is based on a modification of the classification suggested by Patterson *et al.* (1984, 1985).

Type 1: Terrace Bay Batholith-Contact Zone Type

Gold mineralization is concentrated in quartz ± carbonate veins, occupying faults, fractures, and shear zones spatially related to the contact rocks of the Terrace Bay Batholith.

This type of mineralization is described in Patterson *et al.* (1985). During the 1985 field season, approximately two weeks of detailed mapping, at a

scale of 1:2000, was conducted over the Harkness-Hays and Gold Range properties, which are two examples of this style of mineralization.

Harkness-Hays and Gold Range Properties: The Harkness-Hays and Gold Range Properties are located north of Highway 17, in Priske Township, approximately 4 km east of Schreiber. These properties underwent development during a period from 1917 to 1941. Production was 194 ounces of gold from the Harkness-Hays Property from 1935 to 1936, and 17 ounces of gold from the Gold Range Property in 1941 (Marmont 1984). Gold mineralization is concentrated in a series of quartz ± carbonate veins which are generally *en echelon* and can occur subparallel to the contact of the batholith. The most important veins referred to by previous workers are the No. 1, No. 2, No. 3, and No. 7 veins (Resident Geologist's Files, Ontario Ministry of Northern Development and Mines, Thunder Bay).

On the Harkness Hays property, the gold-bearing quartz ± carbonate veins are hosted predominantly by mafic metavolcanics. However, mapping has indicated that in addition to the mafic metavolcanics, the host rocks also consist of quartz-feldspar porphyry and iron formation including chert, massive pyrite sections, and graphitic-pyritic slate.

The iron formation is tightly folded and plunges 58°NE. The presence of up to three adits and numerous old trenches indicates that previous workers explored for gold within the iron formation. Sampling by Sylvanite Gold Mines Limited in 1939 indicated generally discouraging gold values except for assays of 0.08 and 0.16 ounce gold per ton each over 10 cm (4 inches). Analyses by the authors indicated values of 45 ppb gold in the chert, 27 ppb gold in the pyritic-graphitic slate and 65 ppb gold in the massive pyrite sections.

Numerous ages of granitic intrusions were noted on the property, the origins of which are likely due to a polyphase intrusive event related to the emplacement of the Terrace Bay Batholith. The most noticeable phase is a white quartz-feldspar porphyry, which occurs as dikes and is commonly in contact with or partly hosting the vein systems. They appear to be genetically related to the auriferous veins. A reddish biotite-hornblende granite is commonly observed crosscutting the porphyry. Other possible syentitic phases of the intrusion exist.

The rocks in the Harkness-Hays-Gold Range area have been intensely faulted and fractured. This is evident on top of the Gold Range Ridge. Airphoto interpretation indicates a conjugate set of faults striking northeast and northwest. The northwest-striking fault set has apparently offset the Gold Range Ridge, in a dextral sense, up to 0.5 km. There are two prominent lineaments or faults striking northeast that envelop the old development area. Within this 0.5 km by 1 km section, smaller conjugate fault systems strike northwest, east, and northeast. In excess of 25 small-scale lineaments were observed. Field evidence indicates that many of these lineaments represent faults. The vein systems occupying these faults are often brecciated.

A contact metamorphic halo and hydrothermal alteration is particularly well developed where the mafic metavolcanics are in contact with the Terrace Bay Batholith. The aureole is 200 to 300 m in width and often gradational, extending from the contact into the metavolcanics. The auriferous vein systems occur within this zone. The metavolcanics within the contact aureole are generally amphibole rich and contain few primary textures. Near the actual granitic-metavolcanic contact, the metavolcanics resemble a mafic intrusion such as gabbro or diorite. This is believed to be a result of recrystallization during amphibolite facies metamorphism. Outside the contact metamorphic aureole, the metavolcanics are generally chlorite rich and contain numerous primary textures. Typical greenschist facies metamorphism predominates.

In addition to the vein systems described in Patterson *et al.* (1985), other mineralized second-order, composite vein systems striking 70° and dipping nearly vertical were observed hosted in the mafic metavolcanics and in contact with the porphyry dikes. One of the veins ranges up to 2 m in width, but averages <30 cm. Two adits have been developed on the vein and sampling by Sylvanite Gold Mines Limited in 1939 indicated 0.46 ounce gold per ton over 25 cm (10 inches) for 33 m (109 feet) (Resident Geologist's Files, Ontario Ministry of Northern Deveiopment and Mines, Thunder Bay).

A polyphase intrusive event could account for the production of numerous generations of veins, and for causing brecciation of earlier veins along faults, resulting in a reconcentration of gold within secondary or later vein generations.

It seems logical to assume that the fractured metavolcanics acted as conduits for metamorphic-hydrothermal fluids produced during intrusive activity. Furthermore, the intensity of the fracturing could provide enough access for the solutions to leach gold from the volcanic pile. The presence of the sulphide facies iron formation may have been significant, enriching the solutions in iron, possibly producing a sulphidization event. Geochemical evidence from unaltered and altered host rocks indicate that the altered host rocks display carbonatization, sericitization (K_2O enrichment), sodium (Na_2O) depletion, and pyritization.

Type 2: Porphyry Contact Zone Type

Gold mineralization with subsidiary silver, zinc, copper, lead, and molybdenum occur in quartz, carbonate, or quartz-carbonate veins and spatially associated with felsic porphyries. Examples of this type of mineralization occur in the Big Duck Lake area, 30 km north of Schreiber. Quartz, feldspar, and quartz-feldspar porphyries intrude several rock types. The sill-like porphyry bodies strike east-west and dip steeply, 65° to 70°N, and are considered to have formed late in the tectonic history. Pye (1964) suggested that the porphyries are genetically related to the granitic rocks. Mapping by Corporation Falconbridge Copper suggested possible extrusive and intrusive phases of the porphyry, representing a syn-volcanic sublayer intrusion (Patterson *et al.* 1984).

The veins systems are further described in Patterson *et al.* (1985).

Recent work by Corporation Falconbridge Copper has identified numerous gold-bearing zones along the northern contact of the Big Duck Lake Porphyry. The contact area consists of sheared, gradational intrusive to extrusive phases of the porphyry, in contact with predominantly sheared mafic metavolcanics.

Gold values in the sheared, sericitic quartz porphyry and quartz-feldspar porphyry indicate up to 0.13 ounce gold per ton. Minor amounts of molybdenite are also present.

Occurrences include the Nelson Pit, Porphyry Shaft, and North Shore Zone.

Type 3: Metavolcanic Hosted - Dilatant Zone Type

Gold mineralization occurs in quartz and carbonate veins within shear zones, fractures, and cleavage dilation zones within predominantly mafic metavolcanics. Carter (1980a, 1980b) defines these deposits as structurally controlled and related to northwesterly striking shear zones. The gold is associated with silver, copper, zinc, lead, and molybdenum. Numerous ages of veining may be present. The metavolcanic-metasedimentary host rocks generally display sericification and carbonatization. Examples of this style of mineralization may include the Schreiber-Pyramid, Empress, McKenna-McCann, Johnston-McKenna, Morley High Grade, and the Little Bruin (Little Bear) Properties. The Little Bruin and Schreiber-Pyramid Properties might more adequately represent an example of gold concentration related to chemical sedimentary rocks (Type 4). It is possible that an overlapping of genetic models occurred.

McKenna-McCann Property: The McKenna-McCann property is located approximately 5 km northeast of the town of Schreiber, in the central part of Priske Township.

Exploration and development on the property dates back to 1934, with the majority of the work being done by Cook Lake Gold Mines, in the late 1930s, and includes the sinking of a 35 m shaft.

A parallel set of four *en echelon* quartz veins strike to the northwest, varying from 280° to 330° and dip 55° to 70°SW. The zone containing the veins is approximately 25 m wide. The individual veins are lenticular averaging 33 cm in width and have been traced along strike for up to 225 m. They occupy narrow shear zones or shear dilatent zones within a large northwest-trending structure. The shear zones indicate a sinistral sense of motion. The host rock is a highly carbonatized, pillowed metavolcanic rock. Analyses indicate up to 50 ppb gold in the carbonatized metavolcanics. The veins display a crack-seal or ribbon texture, and mineralization consists of chalcopyrite, pyrite, pyrrhotite, galena, tellurides and visible gold. Accessory minerals include chlorite, sericite, and green mica. The fine visible gold commonly occurs along sericite or chlorite slickensides or fractures. Coarse visible gold occurs with chalcopyrite and galena.

Samples collected by the author indicated values from trace to 0.94 ounce gold per ton. This generally supports values of 0.82 ounce gold per ton, obtained from a 12-ton bulk sample collected by Cook Lake Gold Mines in 1938 (Resident Geologist's Files, Ontario Ministry of Northern Development and Mines, Thunder Bay).

Similar vein systems were encountered on the Johnston-McKenna property with scattered, erratic values in gold.

Type 4: Chemical Sediment-Stratabound Type

Gold mineralization can be associated with "Algoman-type banded iron formation" and related chemical and clastic sedimentary rocks. The iron formation and exhalative sedimentary rocks commonly occur at metavolcanic-metasedimentary rock contacts or at pauses between volcanic events. Sulphide facies iron formation predominates in the Schreiber-Terrace Bay area, and these units commonly consist of bedded pyritic-graphitic shale, and massive and laminated chert. Variable amounts of pyrrhotite, chalcopyrite, galena, sphalerite, silver, and gold are present. Gold content within the iron formation is commonly anomalous ranging from 10 to 300 ppb (Resident Geologist's Files, Ontario Ministry of Northern Development and Mines, Thunder Bay). Examples of this style of mineralization include the Kingdom, Simard-Swetz, Little Steel, Black Fox Lake, Morley Pyrite and Morley Road, Otisse, and possibly the Little Bruin and Schreiber-Pyramid Properties.

BASE METALS

Type 1: Volcanogenic Massive Sulphide Deposits

In the Schreiber-Terrace Bay area, base metals are associated with calc-alkalic felsic volcanic rocks. To date, the most significant discovery is that of Corporation Falconbridge Copper on their Winston Lake Property. The property is located 27 km northwest of Schreiber and includes the Zenith Deposit (Zenmac), which was discovered in the late 1800s.

According to Severin and Balint (1984):

> The Winston Lake massive sulphide deposit occurs at the top of the Winston Lake felsic volcanic sequence and is intimately associated with a cherty ash that marks the top of a package of felsic to intermediate volcaniclastics. The sulphide deposit occurs as a relatively thin sheet with an "average" true thickness of 4.3 metres and a length and width of 700 to 800 metres and 300 to 400 metres, respectively.

and,

> Surface diamond drilling suggests a mineral inventory (diluted) of 2,675,000 tonnes of 17.81% Zn, 0.94% Cu, 25.3 gm/t Ag and 0.85 gm/t Au.

The Zenith and Winston Lake deposits are further described in Patterson *et al.* (1985).

Corporation Falconbridge Copper made their official production decision on September 21, 1985, and then suspended development in early November 1985, due in part to slumping zinc prices (Resident Geologist's Files, Ontario Ministry of Northern Development and Mines, Thunder Bay).

If production is reinstated, a 1000 tonne per day mill will be reconstructed at Winston Lake.

Type 2a: Zinc-Lead-Silver Veins - Metavolcanic Type

Zinc, lead, and silver mineralization is concentrated within narrow carbonate and quartz veins within shear zones, faults, and fractures, associated with metavolcanics and metasediments. Mineralization generally consists of massive sphalerite and galena within a banded carbonate vein. Silver appears in concentrations proportional to the galena content. The veins also contain minor chalcopyrite and gold mineralization. Accessory minerals include quartz, epidote, chlorite, sericite, and ankerite. Examples of this type of mineralization include the Deadhorse Creek North, Deadhorse Creek South, Morley High Grade, and McKellar Creek properties.

Type 2b: Lead-Zinc-Barite Veins - Unconformity Type

The lead-zinc-barite veins have been previously investigated by Tanton (1931) and Franklin and Mitchell (1977). The latter classified the lead-zinc-barite deposits of the Dorion property as spatially associated with the unconformity between Proterozoic and Archean rocks.

Franklin and Mitchell (1977) described the deposits as follows:

> The veins are coarse-grained, and mineralogically zoned with galena-calcite in the central zone, sphalerite-quartz surrounding the central zone, and barite (± chalcopyrite) in the vein extremities. Veins occur near the pinch-out of the "Pass Lake Formation" (basal Sibley Group), within the dolomite of the overlying "Rossport Formation", or in the nearby basement fractures. Rossport dolomite, where it forms a vein wall, is highly altered to metal-enriched chert and calcite. Archean wallrocks are not altered.

and,

> The deposits formed from metal leached from either basement rocks or breakdown of Sibley sandstone matrix. Metals and sulphide moved through the permeable sandstone, probably as chlorite-iron complexes, and precipitated at the sandstone pinch-out. Reduced sulphur, possibly derived from organic decay, and probably held in a gas trap at the sandstone pinch-out, caused precipitation of sulphides by reaction with metal-bearing brines.

Examples of Type (2b) include the Enterprise, Ozone, Dorion, Hilma, Silver Lake, Caribou, and Gordon properties.

Type 3: Copper-Molybdenum Vein Type

The copper-molybdenum mineralization occurs in quartz veins, quartz-feldspar offshoots, and aplitic and pegmatitic dikes (Marmont 1984). The veins are generally lenticular, discontinuous and erratic, displaying a banded, laminated, or crack-seal texture. Mineralization consists of chalcopyrite, molybdenite, pyrite, pyrrhotite, silver, and minor gold (generally <0.10 ounce gold per ton). Accessory minerals include chlorite, carbonate, sericite, and hematite. Alteration of the felsic intrusive host rock consists of sericitization, silicification, and hematization.

This type of mineralization is further described in Patterson *et al.* (1985).

EXPLORATION GUIDELINES

Gold

Exploration for gold in the Schreiber-Terrace Bay area should include a thorough re-examination and re-evaluation of past producers, prospects, and occurrences, discovered in the past 100 years.

Properties such as the Harkness-Hays, Gold Range, Hays Lake, and Empress have undergone minor development and production. Recent work on such properties indicates that several ages of veining are present and that complex intrusive and deformational events are related to the emplacement of the Terrace Bay Batholith. Exploration programs concentrating on large scale structures (conduits) or lithological variations where auriferous solutions may have been focused, are recommended. Marmont (1984) recommended detailed structural analyses of the vein systems in an attempt to reveal a more extensive zone of mineralization. The exploration targets for this type of gold mineralization commonly include pyritized host rocks and *en echelon* vein systems, for which an induced polarization survey may prove to be a useful tool.

Numerous auriferous veins are associated with the contact zones and peripheries of intrusions, including the Big Duck Lake Porphyry and Terrace Bay Batholith. Further exploration in these areas as well as in the vicinity of other felsic intrusions is warranted. Northeast and northwest-trending lineaments, such as those recently discovered on the McKenna-McCanna and Johnston-McKenna properties, should be explored and tested in the metavolcanics, metasediments, and peripheries of the intrusions.

Favourable gold target areas include a 4 km by 1.5 km section between Big Duck Creek and Hollinger Lake, and the northern contact of the Big Duck porphyry. Recent prospecting in both areas has discovered numerous vein systems and gold mineralization. Gold potential is also considered high within a 10 km radius of Schreiber, however, it is concentrated within the metavolcanics.

Algoman sulphide and oxide facies iron formation in the Schreiber-Terrace Bay area should be sampled and analyzed for gold in the parts per billion range. Although many of these units contain anomalous yet subeconomic levels of gold mineralization, they may represent protore in the sedimentary-exhalite source rocks. A later concentrating event, possibly related to deformation or intrusive events, could develop economic second-generation deposits.

Base Metals

Exploration for volcanogenic massive sulphide deposits in the Schreiber-Terrace Bay area is recommended in three general areas:

1. Winston Lake-Big Duck Lake Area: Exploration by Corporation Falconbridge Copper discovered a zinc-copper-silver-gold deposit hosted by calc-

alkalic intermediate to felsic metavolcanics in contact with a gabbroic intrusion(s). The host metavolcanics consist of pyroclastic flows, debris flows and laminated ash deposits. Intense hydrothermal alteration of these and associated metavolcanics have been responsible for the misidentification of such indicator rocks. Exploration by Corporation Falconbridge Copper has identified large areas of intense hydrothermal alteration, representing excellent exploration target areas.

2. Santoy Lake-McKellar Lake Area: A large felsic metavolcanic unit trends west-northwest and hosts numerous base metal occurrences including the Marlhill, Goldbar Lake, Bozena, Prairie River, and Granite Mountain properties. Felsic pyroclastic flows were observed in the Granite Mountain area. These clast-supported flows contained considerable garnet mineralization in the matrix component. Felsic metavolcanics in the Fishnet Lake area have been mapped as "andalusite-bearing tuffs" by Walker (1967) and may represent altered rocks. Iron formation and the related chemical and clastic metasediments commonly contain anomalous zinc, lead, copper, silver, and gold concentrations and should be explored.

   Also of economic interest is the Prairie Cove-Prince Point areas where felsic metavolcanics and chemical metasediments have been documented. These felsic metavolcanics may represent a folded extension of the Santoy Lake-McKellar Lake felsic metavolcanic belt.

3. Schreiber Point-Worthington Bay Area: Numerous narrow base metal-bearing veins, gold-bearing veins, and sulphide facies iron formation within mafic to intermediate metavolcanics are present. Sulphide facies iron formation and the related chemical and clastic metasediments appear to represent stratabound chemical exhalative sediments which contains low, however, anomalous concentrations of copper, zinc, silver, and gold. The iron formation units may represent distal parts of volcanogenic base-metal deposits.

   Exploration is recommended within the metavolcanic and metasediments near the western contact of the Port Coldwell Alkalic Complex. Several zinc-lead-silver rich veins have been discovered in this area.

   Exploration is also recommended within the mafic intrusive rocks of the Coldwell Alkalic Complex, as well as the contact metavolcanics. Recent exploration by Fleck Resources Limited on their Marathon property indicates copper, nickel, cobalt, gold, silver, rhodium, platinum, and palladium mineralization.

RECENT EXPLORATION ACTIVITIES

Corporation Falconbridge Copper continued the development of its Winston Lake Deposit (*see* Figure 4.2), including the sinking of a 510 m shaft. The shaft is presently being deepened to 680 m. They recently made their production decision in September 1985, and then suspended development in early November 1985. Work commissioned prior to November will be carried out (Barry Simmons, Manager, Corporation Falconbridge Copper, Thunder Bay, personal communication, 1985). This includes a 3.5 million dollar upgrade of the road, installation of a production hoist, and shaft deepening. Exploration in the Winston Lake area, including the Ciglen, Anderson, and Pick Lake areas continue. Drilling on the Pick Lake zone has encountered "a very thin sheet of high grade material" (The Northern Miner Press, September 30, 1985).

Corporation Falconbridge Copper is also exploring for gold and base metals in the Big Duck Lake area and at the Schreiber-Pyramid property.

Lincoln Resources Limited conducted geological mapping on numerous properties in the Schreiber area, including the Morley property. Exploration in the Morley area included geophysical (Max-Min II, Magnetometer), geochemical, and geological surveys as well as trenching, stripping and sampling. Drilling is slated for early 1986.

PatMikko Resources Limited conducted prospecting, trenching, stripping and sampling on their Johnston-McKenna property. Construction and installation has begun on their small scale gold mill on site.

RTC Precious Metals Incorporated conducted exploration and development on the McKenna-McCann property. Work consisted of geological mapping, trenching, stripping and sampling, including minor ore stockpile development.

Kingdom Resources Limited conducted exploration and sampling on their Kingdom property located in Tuuri Township.

Barracuda Resources Limited conducted linecutting, geophysical surveys, and sampling on its Aguasabon Lake property.

Zahavy Mines Limited conducted drilling on its property adjacent to Winston Lake. Drilling will test for extensions of possible massive sulphide mineralization zones.

Eldor Resources Limited carried out exploration in the Bozena Lake area in Tuuri Township. Base metal and gold mineralization has been previously documented in the area.

Thrust Resources Incorporated conducted geological mapping, prospecting, geochemical surveys, and airborne geophysical surveys on its Santoy Lake Property. The work outlined copper, zinc, molybdenum, and gold geochemical anomalies.

International Wildrose Petroleum Limited conducted sampling, geochemical, and geophysical surveys on their Prairie Cove-Prince Point property. The property is being explored for both gold and base-metal potential. Initial results indicate values of up to 2700 ppb gold and 5700 ppm zinc within chemical metasediments (Ian Campbell, Consulting Geologist, OreQuest Consultants Limited, personal communication, 1985).

Encouraging new discoveries were made by prospectors in the Schreiber-Terrace Bay area in 1985. These include Walter Acker and Russell Otto discovering the Acker Zinc Occurrence north of Sox

Lake. Zinc and copper mineralization is present within sheared and silicified metavolcanics.

Ray Mikkonen, Tom Patterson, and the authors rediscovered several vein systems on the Johnston-McKenna property. Assay results indicate encouraging but erratic gold values.

RESEARCH ACTIVITIES IN THE SCHREIBER-TERRACE BAY AREA

B.R. Schnieders, part-time graduate student, Lakehead University, Thunder Bay, continued research on sulphide-facies iron formation units as part of an M.Sc. thesis. Research began in late 1983 and will continue into 1986. Research in 1984 included detailed mapping, logging, sample collection and preparation, detailed structural analyses and stratigraphy of confined sections. In 1985, further detailed investigation of iron formation occurrences was carried out. Laboratory work includes microscopic examinations, whole rock geochemistry, and X-ray diffraction studies.

ATIKOKAN COBALT–BASE METALS–PLATINUM–GROUP ELEMENTS PROJECT by A.D. MacTavish and R.J.A. Dutka

INTRODUCTION

The Atikokan Cobalt-Base Metals-Platinum-Group Elements Project is presently in its second year of a proposed three-year tenure and is staffed by A.D. MacTavish and R.J.A. Dutka, Resource Geologists. The objectives of the program are:

1. To stimulate exploration for the base metals, cobalt, the platinum-group metals, and gold in the Atikokan Area.
2. To assist prospectors and junior mining companies in the area with property visits, advice, and literature searches.
3. To assist the mining companies interested in conducting exploration programs in the area by providing up-to-date information and files on the area's mineral occurrences.

The program to date has consisted of detailed mapping, sampling, assaying, and some petrographic work on the significant cobalt, base-metal, and platinum-group metal occurrences. Emphasis, in 1985, has been placed on the iron-copper-nickel-cobalt prospects within a 28 km long part of the Quetico Fault Zone; and the copper-nickel-platinum-palladium occurrences within the mafic to ultramafic plugs and sills in the Crooked Pine Lake area east of Atikokan. Five occurrences were mapped in detail. Property examinations for documentation and sampling purposes were done on four other cobalt, base-metal or platinum-group metal occurrences and nine gold occurrences in the general Atikokan area. Several informal field trips were conducted at the request of interested parties from the Ontario Geological Survey, private industry, and Lakehead University.

At the program's end, a report with maps will be prepared to document the location of all occurrences visited and to document their geological setting, petrochemistry, assay results, and mineral potential. Special emphasis will be placed on those areas that were examined in detail. Mineral and rock suites are in preparation for display at the Resident Geologist's Office in Thunder Bay and at the Ontario Geological Survey's Geoscience Seminar in Toronto.

GENERAL GEOLOGY AND STRUCTURE

The project area lies within the southern part of the Superior Province of the Canadian Precambrian Shield. The general geology and structure are described in Patterson *et al.* (1985).

DEPOSITS TYPES

In Patterson *et al.* (1984), the presence of five preliminary deposit types which might host cobalt, base-metal or platinum-group metal mineralization were described. These deposit types remain as stated except for "Type 1" which has been renamed the Atikokan River Intrusions rather than the Quetico Fault Zone-hosted Intrusions. This name change was made to avoid confusion with deposit Type 2, "The Quetico Intrusions". The five deposit types are now:

1. The Atikokan River Intrusions
2. The Quetico Intrusions
3. Chemical Metasedimentary Rocks
4. Shear Zones
5. Quartz Veins

Detailed geological mapping and sampling on examples of the deposit types 1 and 2 during the 1985 field season, are discussed below.

1) The Atikokan River Intrusions

Along 28 km of its length, from Crooked Pine Lake west to Atikokan, the Quetico Fault Zone, where it forms the Atikokan River valley, is host to six very similar-appearing, syntectonic, mafic to ultramafic intrusions. These intrusions are dike-like in appearance, very resistant to erosion, and in most cases form high, steep-sided ridges. Rock composition ranges from hornblende melagabbro to serpentinite. Syntectonic emplacement has resulted in almost pervasive shearing, the amount of which increases from the centre of the intrusions outward. Slickensides are common and the original texture of the rock is destroyed near the contact with the fault rocks. Fault-bound blocks and lenses of massive to semi-massive as well as disseminated magnetite are ubiquitous, and lenses and zones of occasionally fault-bound, disseminated to massive pyrrhotite, pyrite and chalcopyrite are also common. Net-textured pyrrhotite and chalcopyrite have been observed locally. Subsequent shearing has largely remobilized the sulphide mineralization. Three of the intrusions were mapped in detail in 1985, two of which are described below.

The Atikokan Iron Mine The Atikokan Iron Mine is located on Mining Locations E10, E11 and E12, in Hutchison Township, approximately 24 km east of Atikokan and about 1200 m east of Sapawe Lake.

The deposit was discovered in 1882 and has had a long mining and exploration history. By 1890, an exploration shaft was sunk and the first speculative

tonnage of 2 000 000 tons of iron ore was stated (Resident Geologist's Files, Ontario Ministry of Northern Development and Mines, Thunder Bay). A number of diamond-drill holes, an adit, and numerous trenches were completed between 1899 and 1905. Active mining commenced in late 1905 and continued intermittently until production ceased in 1913. Production during that time is reported to have been 86 433 short tons of ore grading an average of 59.85% iron and 2% sulphur (Resident Geologist's Office, Ontario Ministry of Northern Development and Mines, Thunder Bay). From 1913 until the present, sporadic exploration activity has taken place including: bulk sampling for metallurgical analysis, diamond drilling, airborne and ground geophysics, and geological mapping and sampling. Prior to 1950, exploration activity was related to iron, however, since that time interest has shifted to copper, nickel, and cobalt. Recently, the mine has been re-examined for platinum-group metal content.

This abandoned deposit is contained within a high, steep-sided, erosion resistant, dike-like mass 1100 m long and up to 100 m wide, surrounded by low swampy ground. Lithologies observed range from sheared hornblende melagabbros and serpentinized peridotite (field term), to massive and sheared serpentinite containing isolated asbestos seams and veins. Structurally, the intrusion is complex with an intricate pattern of faults and shear joints. Slickensides are common and well developed. The ultramafic rocks within the thin fault zones are dynamically altered to chlorite schists, chlorite-sericite schists, or serpentine schists. Hydrothermal activity has locally resulted in intense silicification and carbonatization producing carbonate, silica-carbonate, and silica flooded zones. Some of the hydrothermally altered zones can resemble deformed, iron-rich, chemical sediments or chert-carbonate beds.

Mineralized zones are usually composed of fault-bound blocks and lenses of massive magnetite, sulphide-bearing massive magnetite (1% to 20% pyrrhotite and chalcopyrite), semi-massive to massive pyrrhotite with some chalcopyrite, and mineralized and sheared ultramafic rocks containing 5% to 50% pyrrhotite and chalcopyrite. Variable amounts of finely disseminated magnetite (1% to 10%) are present in most rock types and all sulphide-bearing zones. Analysis of 19 samples has returned values that range from 35.7% to 57% iron, 430 ppm to 2670 ppm copper, 50 to 650 ppm (1.30 pounds per ton) cobalt, 120 to 760 ppm nickel, and in one sample 1.06% zinc (assays by the Geoscience Laboratories, Ontario Geological Survey, Toronto).

Pattison-Roberts Prospect The Pattison-Roberts Prospect is located on Mining Locations R403, R404 and X212 in McCaul Township, near the southern bank of the Atikokan River, approximately 12 km east of Atikokan and 4.2 km west of Sapawe Lake.

This prospect was discovered circa 1882 as a direct result of the discovery of the Atikokan Iron Mine Deposit. In the period between 1890 and 1970, a total of 24 rock and overburden pits, trenches, and shallow shafts were excavated. In addition, exploration consisted of diamond drilling, roasting and metallurgical testing, and some ground geophysics.

The iron-copper-cobalt-nickel mineralization, similar to that of the Atikokan Iron Mine, is contained within a high, steep-sided, very erosion resistant, dike-like mass approximately 850 m long and up to 100 m wide. Rock types observed range from a fine-grained carbonate-chlorite schist to a predominant, sheared and serpentinized ultramafic rock tentatively termed a peridotite. Locally, seams of asbestos were observed, in larger quantities than at the Atikokan Iron Mine. Faults are numerous, but due to the poor exposure, their extent is unknown. Carbonate-chlorite schists and slickensides are the direct result of excessive shearing at the edges of the dike and also tend to characterized the smaller more localized subconcordant and cross-cutting faults. Carbonate stringers are common.

Magnetite, pyrrhotite, pyrite, and minor chalcopyrite, in amounts <2%, are very finely disseminated throughout the dike. Semi-massive to massive, possibly fault-bound, pods or lenses of magnetite are common near the southern edges of the dike and can contain 5% to 15% pyrrhotite, pyrite, and chalcopyrite. The eastern part of the dike contains tectonically banded, massive zones of pyrrhotite, up to 30 m thick, that locally contain 10% to 50% disseminated to semi-massive chalcopyrite and 1% to 15% very finely disseminated magnetite throughout. Assays of 17 samples returned values that range from 43.9% to 56.8% iron, 680 ppm to 2.7% copper, 490 ppm to 0.279% nickel, 114 ppm to 2380 ppm (4.76 pounds per ton) cobalt, and one sample that returned 4245 ppm titanium (assays by the Geoscience Laboratories, Ontario Geological Survey, Toronto).

Sheared and mylonitized clastic metasediments are present south of the dike. These rocks grade from moderately sheared turbiditic greywackes to highly sheared chlorite-quartz-sericite schists to biotite-sericite phyllonites. The phyllonites appear to be the most dynamically deformed rocks in this part of the Quetico Fault Zone and probably define the centre of the zone.

A relatively unmineralized, sheared, hornblende gabbro dike is located about 50 m north of the mineralized dike. It is fairly uniform in composition and contains about 1% to 2% finely disseminated pyrrhotite and chalcopyrite. The edge of the dike is highly sheared, carbonatized and silicified, and altered to quartz-carbonate-chlorite-sericite schist. This body does not appear to be a displaced part of the mineralized dike, and is probably a later, more fractionated intrusion.

2) The Quetico Intrusions

Intruded into the thin belt of metaturbidites that make up the northern Quetico Subprovince is a series of superficially similar mafic to ultramafic dikes, sills, plugs, and stocks. They occur within a 95 km long zone between McOuat Lake in the west and Lac des Mille Lacs in the east and range in size from 100 m by 30 m to over 850 m in diameter. Thirteen of these have been examined in the Atikokan area, two in detail. Lithologies include hornblende leucogabbro to

hornblende melagabbros, feldspathic hornblendite, and hornblendite. Occasionally the larger intrusions contain zones of pyroxene hornblendite, hornblende pyroxenite, and pyroxenite. They are usually multiphased and appear to be roughly concentrically zoned. Textures range from fine to very coarse grained to pegmatitic. Cumulate layering has been observed locally. Detailed mapping and sampling have been completed on the Mud Lake and Abiwin Intrusions.

Mud Lake Intrusion The Mud Lake Intrusion is a comma-shaped sill-like body over 800 m long and between 10 and 100 m wide. It is located on the western shore of Mud Lake about 40 km east of Atikokan and 500 m south of Crooked Pine Lake. The intrusion has been mapped in detail for a distance of 350 m west of Mud Lake, covering the thickest and most highly mineralized part of the sill. This mafic to ultramafic body has been emplaced by two apparently separate intrusive episodes.

Initially, a modally layered ultramafic cumulate composed of discontinuous and disrupted, very coarse grained, oikocrystic hornblendites, feldspathic hornblendites, and porphyritic hornblende melagabbros was emplaced. After partial cooling, a fine- to coarse-grained, relatively massive, ophitic and sometimes pegmatitic hornblende gabbro to leucogabbro was intruded sub-concordantly on top of the ultramafic cumulate. The presence of very coarse grained gabbro pegmatite pods and veins throughout all rock types implies that later volatile-rich fluids moved along available pathways such as shears, fractures, and joints after the mafic and ultramafic rocks had at least partly cooled.

During, or possibly after the emplacement of the sill, regional amphibolite grade, dynamo-thermal metamorphism produced a quartz monzonite to granodiorite intrusive mobilizate by anatectic melting. In addition, sill emplacement produced a thin contact metamorphic aureole, 2 to 5 m wide in the surrounding turbiditic metasediments. Intrusion of the mobilizate formed a metasedimentary migmatite above the sill and in a few areas below the sill. Later the sill was folded and then faulted. Two major east-west faults have had their effect: one has dextrally offset the northern limb of the intrusion approximately 125 to 150 m to the east, while the other has produced an intense shear zone 30 to 50 m wide in the metasediments just south of the intrusion. The action of these two faults has produced, within the intrusion, a series of small scale right-lateral and left-lateral faults striking between 135° and 160° with offsets ranging between 0.10 m and 3 m.

The largest sulphide concentrations, usually of 2% to 20% finely disseminated pyrrhotite, chalcopyrite, and pyrite, occur in irregular pods, 5 to 10 m long and 2 to 5 m wide. Sulphide mineralization is also present in small patches of 1% to 5% finely disseminated pyrrhotite and chalcopyrite throughout all rocks types and as a fairly uniform, <1%, finely disseminated pyrrhotite and chalcopyrite in the hornblendite layers and in the ophitic hornblende leucogabbro mass. The gabbro pegmatites tend to concentrate sulphide mineralization and can contain up to 15% disseminated pyrrhotite and chalcopyrite. In addition, these pegmatites locally contain high percentages of scheelite ($CaWO_4$) in amounts approaching 10%. Scheelite was also observed in thin quartz-carbonate stringers in feldspathic hornblendite and porphyritic hornblende leucogabbro.

Assay results values range from trace to 3.45% copper, trace to 920 ppm nickel, trace to 0.27% tungsten, and one sample with 95 ppb platinum and 115 ppb palladium.

Abiwin Intrusion The Abiwin Intrusion is a small, highly deformed, dike-like body approximately 200 m long and between 20 and 40 m wide. It is located about 37 km east of Atikokan, 2.8 km northwest of Nydia Lake and on the north shore of a small unnamed lake. It is composed of slightly to highly altered medium to coarse-grained hornblende gabbro, hornblende melagabbro, feldspathic hornblendite, and hornblendite hosted by metasedimentary migmatites. The dynamic and thermal processes which have formed the migmatites have had a marked effect on the intrusion. By nature, the rocks composing the Abiwin Intrusion are very competent and tend to react brittley (fracturing and brecciation) to shear stress, while the metasediments react in a ductile manner (shearing). Thus, the formation of the migmatites has produced pull-apart structures within the dike, locally causing it to appear truncated faulted, rotated, or elongated.

Mineralization consists of numerous small, irregularly-shaped pods up to 10 m in length and 2 to 3 m in width and one larger pod nearly 40 m long and 10 m wide. The pods are contained within feldspathic hornblendite and hornblendite and are composed of 2% to 35% disseminated pyrrhotite, pyrite, and chalcopyrite. Analysis of polished thin sections have shown the existence of some very small discrete grains of some as yet unidentified platinum-group minerals, possibly sperrylite ($PtAs_2$) and merenskyite ($PdTe_2$). Assays indicate between 103 ppm and 2.20% copper, 116 ppm and 0.28% nickel, 50 ppm to 205 ppm cobalt, 30 ppm to 0.11 ounce per ton palladium, and 25 ppb to 1.15 ounces per ton platinum.

EXPLORATION GUIDELINES

The following guidelines might be useful in locating deposits that are associated with, or similar to, the two deposit types previously described.

Type 1 - The Atikokan River Intrusions: These iron-copper-nickel-cobalt-(asbestos) occurrences and deposits exhibit certain properties and associations which could facilitate discovery of similar bodies elsewhere:

a) They have an intimate association with intense well defined transform fault zones.

b) They are very resistant to erosion and tend to form high, very steep-sided linear ridges.

c) Due to their high magnetite content, they exhibit a significant and well defined magnetic signature.

d) Their high, conductive-sulphide content tends to produce good, linear, electromagnetic anomalies.

Type 2 - The Quetico Intrusions: These copper-nickel-platinum-palladium-(tungsten) occurrences are not as readily discernible as the "Type 1" deposits. However, they have three common or distinguishing features:

a) They occur as small isolated bodies within the relatively thin belt of turbiditic metasediments that comprises the northern part of the Quetico Subprovince.

b) They are slightly more erosion-resistant than the surrounding metasediments and occur as topographic highs.

c) They exhibit a distinctive, relatively isolated and intense, high magnetic anomaly with a flanking magnetic low. In some cases, this magnetic signature should be discernible even when the intrusion is mantled by a thin cover of metasedimentary rock.

Government geology and geophysical maps are available for the above-described areas.

SUMMARY

Cobalt, base-metal and platinum-group elements mineralization has been assigned to five "deposit types" based on lithology, structure, and associated sulphide mineralogy. Two of the five deposit types were examined in detail during the 1985 field season:

1. "The Atikokan River Intrusions" contain significant cobalt, copper, nickel mineralization closely associated with massive magnetite within highly sheared, structurally very complex, syntectonic, ultramafic intrusive rocks. A similar potential for cobalt and base metals may exist within other intrusions of this type.
2. "The Quetico Intrusions" are relatively small, mafic to ultramafic bodies exhibiting high, local concentrations of copper, nickel, cobalt, platinum, palladium and in at least one intrusion, tungsten mineralization. Base-metal and, in particular platinum-group element potential, is high in these and other similar bodies and should be investigated.

Work planned for 1986 will include geological mapping and sampling of one more Type 2 deposit, the Kawene Intrusion, and one example of each of the remaining deposit types which have not yet been examined in detail. Reconnaissance mapping and sampling for documentation purposes will continue, as will any property examinations requested by prospectors and mining companies.

HISTORICAL RESEARCH PROJECT

The Regional Mineral Resources Co-ordinator's Office continued its historical research project initiated in 1981. This project is an in-depth search of the old literature (mining journals, newspapers, magazines, government reports, etc.) for information on mineral occurrences and mining activities in the Thunder Bay Mining Division.

Each article is copied, referenced, and filed in the Mineral Deposits Files in the Resident Geologist's Office, Thunder Bay. In 1985, research was concentrated on: The Northern Miner, covering the time period from January 3, 1935 to December 28, 1939; and The Daily Journal (Fort William paper) covering the time period from January 10, 1894 to December 20, 1900.

RESULTS

1. Valuable information has been added to the files on documented and undocumented gold occurrences in the Atikokan, Beardmore-Geraldton, Shebandowan, and Schreiber-Terrace Bay areas. An example of an undocumented occurrence follows:

   Mr. James Hammond and a few other gentlemen have formed a company to be called the Kabaskong Gold Mining company. The company has acquired the south half of mining location 361X on Sawbill Lake (now Marmion Lake, north of Atikokan). The celebrated Hammond-Folger dyke or reef cuts through this location from the north-east towards the south-west. Several hundred feet of the reef on the company's property was uncovered late last fall and several test pits were sunk by it. The portion of the reef on the company's on the company's property appears to be about 2,000 feet in length by, in the neighborhood of, 200 feet in width . . . .

   An assay made on the 20th December, 1896, at the School of Mines, Kingston, of a general average of the rock taken from two test pits sunk on the reef on the company's land yielded $6.04 of gold and 20 cents of silver per ton. [The Daily Journal, Feb. 2, 1897]

   Reports from the Kabaskong Mine state that a discovery of a splendid quartz vein has been made on the reef. The vein is said to be five or six feet wide and from some of the ore which was panned by Mr. Hammond, it showed gold in a nice quantity, indicating that it is highly mineralized. [The Daily Journal, Mar. 13, 1897]

   A meeting of the directors of the Kabaskong Mining Company was held . . . . The report of Prof. Hille who examined the property was received with diagrams and maps showing the amount of work done and the result of his examination. The tunnel is now in 96 feet and the assays made by Prof. Hille gave the following results: $3, $10, $30, and $41. The first assay is the lowest, which was obtained. It came from the dyke and the highest from pit No. 4 in the north half which was down 16 feet at the time. The vein is 11 feet wide, but is lined on each side with broken schist and leaves a gangue of five or six feet carrying free gold and is highly mineralized. Prof. Hille estimates that the ore on the dyke can be mined and milled for $1.25 per ton and the lowest assay he got was $3.00 [The Daily Journal, Oct. 9, 1897]

2. Some articles contain glowing descriptions, but they should be checked out.

   Example 1:

   Fourteen years ago, Mr. Joe Weiden, of the Mission, discovered a rich vein of silver on the Payplat River, one-and-a-half miles from Lake Superior, one-and-a-quarter miles from the C.P.R.

main line, and about midway between Rossport and Payplat siding.

About three years ago, Mr. Weiden sold the controlling interest to John King, the enterprising general merchant of this place, and that gentleman has since that time had men doing a little prospecting on the property . . . .

On that date, while prospecting, a vein was struck which for richness is equal to anything ever found in the district before, and the place where it was found was only about three or four hundred feet from the spot where Capt. Weiden had been prospecting for months and had only been able to find silver assaying from $10.00 to $25.00 to the ton.

The vein where the big find was made is ten feet wide and may be followed for one half of a mile. It is a veritable wall of silver, from which huge chunks may be detached by the use of a common miner's pick, and it is estimated that no less than $800,000 worth of silver is in sight at this place.

Capt. Weiden brought samples of the rock to Fort William, and Mr. Peter McKellar assayed them and found that they were sufficiently rich to reach the enormous figures of from $2,500 to $10,000 to the ton of native silver and a button of the precious metal, made from the samples for assay, was seen by a reporter. [The Daily Journal, Dec. 2, 1895]

Mr. Joseph Weiden has sold his interests in location R570, 594, 576, 577 and 578, north of the Pays Plat Indian reserve to Mr. Jno King. [The Daily Journal, Nov. 17, 1896]

The above area was open for staking, as of December 11, 1985.

Example 2:

Another property has now come to the front in Algoma in the Fire Mountain, known as 362X, which was discovered by Mr. W.H. Arnold about the *middle of October* and is situated 1 1/2 miles from northeast of Steel Lake siding, 160 miles east of Port Arthur. This property is something unusual in the mining discoveries of Algoma, as it appears to be nothing short of a gold quarry, one wall only being discovered yet, which is at the base of a mountain, the mountain formerly having no name, but was named by the discoverer. The quarry is one half mile long, following the mountain its entire length, and at present the ore is of a state formation, highly mineralized and carrying galena, copper and iron pyrites in good quantities. Assays have been made and they run from $1.50 to $40 per ton gold. [The Daily Journal, Dec. 5, 1896]

THUNDER BAY DRILL CORE LIBRARY by G.D. White and P. Hinz

Construction of the Thunder Bay Drill Core Library was initiated in May and completed in October of 1985. The official opening will take place in the spring of 1986. To date, approximately 30 400 m of core are stored in the facility (which has a capacity for about 137 000 m), with an additional 8500 m stored at three temporary sites in the field (Table 4.6). Flatbed trucks, that can hold approximately 5480 m of core, were used to transport the core from these temporary field locations to Thunder Bay. Core was obtained through voluntary donations and soliciting of companies active in the Thunder Bay Region. An up-to-date list of all companies and prospectors active in the area is maintained through contact with the Economic Geologist Programs, Ontario Geological Survey field geologists and through work permits and assessment data submitted to the Resident Geologist. Computer compilation of all data is in progress.

For the purpose of providing easy access to and cataloguing of core samples, the Thunder Bay Region has been divided into four areas: 1) West: Atikokan-Shebandowan, 2) East: Schreiber-Terrace Bay, 3) North: Beardmore-Geraldton, and 4) The Hemlo Area. This provides for easy access and cataloging of all core samples. It is hoped that this facility will be used by mining companies, prospectors, and academics for detailed follow-up studies, property acquisitions, and thesis work. Equipment required for core splitting, chemical testing, and microscopic examination are available at the Drill Core Library. Detailed files on logs, geochemical testing, and drillhole locations are maintained for all properties.

Unlogged drill core will be documented by Library staff and the data will be accessible to the public.

The Drill Core Library is presently staffed by G.D. White and Assistant, P. Hinz. All inquiries relating to the facility may be directed to: Drill Core Library, Ontario Ministry of Northern Development and Mines, Euclid Avenue, Thunder Bay, Ontario, P7C 5G6, or by calling (807) 475-1331.

BUILDING AND MONUMENT STONE by M.C. Kennedy and P.M. Gertzbein

INTRODUCTION

The "Building Stone Inventory" project was initiated in April 1984 to encourage the development of the dimension stone industry in the North Central Region. It is a two-year project funded jointly by the Federal and Provincial Government under the Northern Ontario Rural Development Agreement (NORDA), and is staffed by Myra Kennedy and Paul Gertzbein, Resource Geologists. The primary goals of the program are to identify areas and rock types having high potential for the production of good quality building and monument stone and to make information on all aspects of the stone industry available to the private sector.

Project activities have included identification and detailed documentation of occurrences of good quality stone as well as reconnaissance mapping in areas of high potential. Stone samples are cut and polished and are available for viewing at the Thunder Bay Resident Geologist's Office. Physical testing, chemical analysis, and petrographic work have been carried out on selected samples. Prospectors have received assistance in the form of property visits, sample preparation, information about the stone industry, and assistance making business contacts. The pro-

BREAKDOWN BY AREA

WEST: Atikokan-Shebandowan	8 360 m
EAST: Schreiber-Terrace Bay	3 355 m
NORTH: Beardmore-Geraldton	16 670 m
Hemlo Area	10 515 m
Total Core Collected	38 900 m

ject has also involved promotion of stone from the area. Samples have been shown to stone producers in Minnesota and Quebec, and incorporated into a display of Ontario stone exhibited at the Canadian Wood Energy Institutes Trade Show in Toronto in June 1985. A display of Northwestern Ontario stone was presented at the Minnesota Society of the American Architects Association Annual Convention in Minneapolis in November 1985.

Renewed interest in stone from this area and increased activity in stone exploration is a result of this project. Several granite and sandstone properties have been staked. Interest has also been shown in decorative stone and crushed stone for the production of aggregate panels.

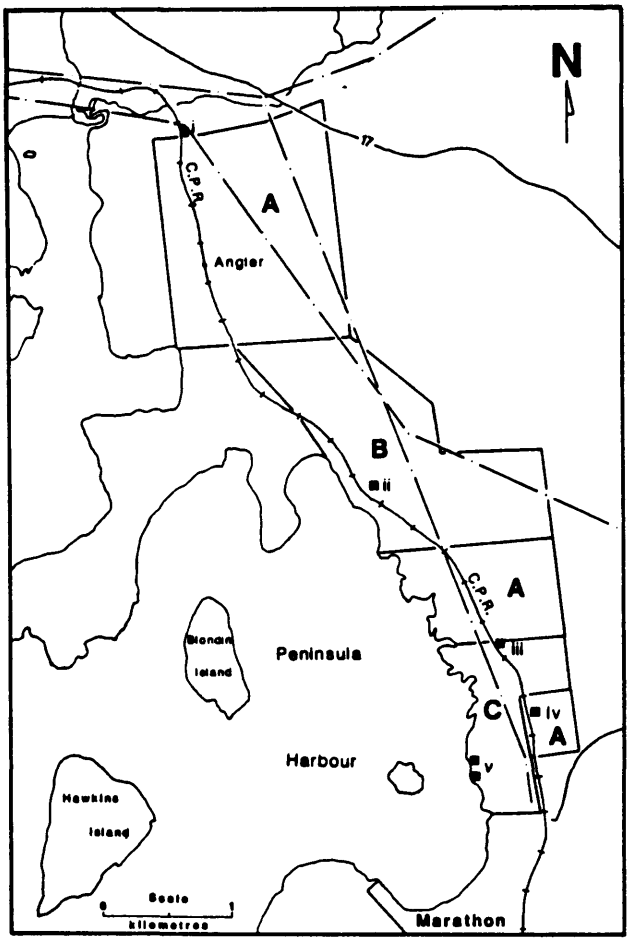
The reader should note that the terminology used in the stone industry differs from standard geological terminology. Terminology and geological criteria for stone deposits are described by M.C. Kennedy and P.M. Gertzbein *in* Patterson *et al.* (1985).

GRANITE

The area underlain by the Coldwell Alkaline Complex on the north shore of Lake Superior appears to have the greatest granite dimension stone potential in the North Central Region. In particular, the dark-coloured and red syenites of the complex are suitable for building and monumental purposes. The accessibility of parts of the complex by road, rail, and water is also a factor favouring this area.

The dark green-brown (black) augite-amphibole syenite (Currie 1980) covers a large area of the Coldwell Complex. This homogeneous, medium to coarse-grained rock was termed "laurvekite" by Puskas (1967). It is predominantly composed of alkali feldspar, pyroxene, and amphibole. The "barkevikite syenite" (Currie 1980) is a medium- to coarse-

Figure 4.6 . Dimension Stone Properties – Marathon Area



1985 PROPERTIES	LOCATION OF PAST PRODUCING QUARRIES
(A) Noranda	i. Angler Quarry
(B) D.Petrunka	ii. Red Syenite Quarry (Peninsula G.Q. Co. 1929)
(C) James River-Marathon Ltd.	iii. Augite Syenite Quarry (Coldspring 1930)
	iv. Augite Syenite Quarry (C.P.R. 1880's)
	v. Augite Syenite Quarry (Peninsula G.Q. Co. 1929)

grained intrusive rock, which is brown to red in colour. It is composed predominantly of alkali feldspar (commonly perthitic) and barkevikitic amphibole which can be seen as acicular grains in hand specimen. The area north of the town of Marathon is underlain by these two rock types and is the site of past dimension stone production. A number of the old quarries are located on Figure 4.6.

History

Black syenite was first quarried by the C.P.R. near Peninsula Station (now Marathon) in the 1880s for bridge construction. In 1927, Peninsula Granite Quarries Company began the first commercial quarrying in the area. The company held 17 claims along the C.P.R. and the shore of Lake Superior north of Peninsula Station. Quarrying of black and red syenite as carried out at several sites. The black granite property was sold to the Cold Spring Granite Company of Cold Spring, Minnesota in 1931, who operated a quarry for two years. During this period, a small amount of red and black syenite was also produced near Angler, 6 km north of Peninsula by Angler Granites Limited. Prospecting for granite near Middleton and Coldwell, to the west along the C.P.R., also took place at this time. In 1960, the Lake Superior Stone Syndicate staked 47 claims in the area with plans to begin quarrying. Failure to secure the necessary market for the stone resulted in the termination of the project (Puskas 1967).

Current Activity

Exploration activity for dimension stone in the area north of Marathon has been renewed in the past 18 months (*see* Figure 4.6 for current property ownership). Noranda Incorporated holds ground adjacent to the Angler quarry, the former Cold Spring quarry, and the old C.P.R. quarry. These are predominantly areas of "black granite" or augite syenite. The southern part of the Angler group of claims is underlain by red to brown syenite. Noranda Incorporated has carried out geological work on these claims. D. Petrunka staked a group of claims encompassing a "red" syenite body (actually brown) located south of Angler on which drilling is soon to begin. Three of the old quarries are located on patented ground owned by James River-Marathon Limited, the paper company in Marathon. Petrunka has also staked a group of claims on red syenite along the Trans-Canada Highway near the village of Coldwell, to the west of this area.

These properties possess characteristics that make them potential sources of building and monument stone. The dark and red syenites polish well, exhibiting attractive colours and textures. The dark green-brown syenite appears black when polished. The brown and red shades of the barkevikite syenite staked by Petrunka are very attractive when polished. Black, brown, and red coloured stones are currently in demand. Physical testing results indicate that the syenites meet A.S.T.M. (American Society of Testing and Materials) standards for granite dimension stone.

The Marathon area hosts a number of properties in which the rock appears to be structurally suitable for quarrying. Joints should be absent or widely

spaced, and orthogonal to permit the extraction of large, straight-sided blocks. Several promising sites are located near former quarries in the area. In some cases, the former quarries are located in what the author would consider to be relatively poor areas. Past operations did not require blocks of the size which are desirable today (20 to 25 tons) and, therefore, stone was removed from areas with closer spaced jointing. Some of the most favourable areas for quarrying are: the site of the old C.P.R. quarry; the area just east of the old Cold Spring quarry; an area north of the Angler quarry between the powerline and Hare Creek; many parts of the red syenite body but particularly an area just south of the old Peninsula Granite Company quarry; and parts of the red-brown syenite south of the Angler quarry. The red syenite near Coldwell also appears to be suitable for quarrying. Jointing is widely spaced and sheets 4 to 5 m thick were observed.

SANDSTONE

The first dimension stone to be produced in the North Central Region was sandstone from Sibley Group sediments of Proterozoic age. Red- to brown-coloured sandstone of the Rossport Formation was quarried at Vert Island and La Grange Island in Nipigon Bay in the early to mid-1880s. Cream or buff-coloured sandstone of the Pass Lake Formation was quarried at Simpson Island, Quarry Island, and in the Wolf River area in the mid-1880s and early 1900s. Several buildings in the City of Thunder Bay were constructed of the sandstone from Vert Island and Simpson Island in the early 1900s. The present condition of the stone in these buildings attests to the durability and lasting beauty of these sandstones.

Vert Island Sandstone Quarry

Red sandstone was produced from Vert Island in Nipigon Bay of Lake Superior in the early 1880s by a Chicago company. The stone was shipped to Chicago and the mid-western U.S. until the mid-1880s when an import duty imposed on sandstone by the U.S. government made it uneconomical. The sandstone was used in 1885 in the construction of the C.P.R.'s Nipigon River bridge. The site lay idle until the early 1900s when Fort William and Port Arthur contractors removed previously quarried stone from the island for local building construction.

The quarry is located on the west shore of Vert Island on patented land. The site is overgrown but can be spotted by the presence of four stone rubble promontories which are the remnants of docks. The quarry face is approximately 225 m in length and averages 8 m in height. The stone along the length of the quarry appears to be of excellent quality. It is an attractive brick red colour and quite homogeneous in colour and texture. White reduction spots and streaks occur but do not seem to mar the appearance of the stone. Large blocks of stone could be extracted. Near-surface horizontal fractures are closely spaced but these widen to 1.5 to 2 m at a depth of about 2 m on most faces. Vertical joints are commonly 1.5 to 2 m apart.

The Vert Island sandstone used in local buildings is in very good condition showing little or no deterioration and none of the black discolouration which is common in red sandstones. The site could be an excellent source of sandstone ashlar as well as yielding large blocks for construction.

Simpson Island Sandstone Quarry

Buff-coloured sandstone was quarried on the north side of Simpson Island in Lake Superior in the early 1900s. The sandstone (quartzite) is predominantly thinly bedded, splitting into slabs 2.5 to 5 cm thick. Some sections would allow extraction of slabs 50 to 75 cm thick. The sandstone is exposed along the old quarry face which is 75 m in length and up to 14 m in height. The size of the deposit is difficult to estimate as the area is heavily tree covered. Near the quarry, the light-coloured unit is overlain by red pebbly sandstone. There may be about 30 m of the light-coloured sandstone above water level. It is exposed for a short distance to the west of the quarry. Overburden covers this unit to the east although it is found at other locations on the north shore of Simpson Island (Giguere 1975).

The property was staked in May, 1985, by W. Seeber of Thunder Bay, who is examining the feasibility of producing sandstone flagging and ashlar from the site. Seeber is also examining the silica potential of the sandstone in this area and has staked a past-producing property on Quarry Island near Rossport. A sample of the Quarry Island sandstone, sent for analysis by the author to the Geoscience Laboratories, Ontario Geological Survey, Toronto, contained 99.0% SiO_2. Seeber is conducting further analysis.

ORNAMENTAL STONE

"Marble" in the Thunder Bay area occurs as a carbonate-rich part of the Sibley Group, in a variety of colours and is particularly suitable for ornamental purposes. The LunMac "marble" property located near Eaglehead Lake has been described in detail by Redden (1980, Assessment Files of the Resident Geologist office, Ontario Ministry of Northern Development and Mines, Thunder Bay), Fenwick and Scott (1977), and Patterson *et al.* (1985). The "marble" is multi-coloured (grey, white, brown, green) but the predominant unit is a 3 m thick layer of blue-grey stromatolitic dolomite. The stromatolitic unit makes particularly distinctive ornamental stone and is available in some quantity. H. Lundmark and W. McAteer make ornamental objects (clocks, pen sets, etc.) of the marble which are sold locally. The marble has also been used for decorative flooring and wall facing.

Pink to coral-coloured marble is found near Ouimet at the former site of the Black Bay Mine and Quarry Company (1880s) and layered, green marble occurs near Muskrat Lake.

Amethyst breccia from amethyst-producing properties in the Thunder Bay area makes attractive stone for decorative wall facing and fireplaces.

Several other locations demonstrate potential for decorative stone deposits. These include the dolomite breccia found at the Steeprock Iron Mine, graphic granite found north of Thunder Bay on Highway

527, and red stromatolitic jasper found at Mink Mountain.

RECOMMENDATIONS

A number of potential stone deposits have been located in the Coldwell Complex. There remain areas of the complex to be examined which also have good potential. Some of the other rock units (e.g. nepheline syenite) should be examined for their suitability.

Other granitic intrusions also make good exploration targets for dimension stone. Examples include the Eva Lake Stock near Atikokan and the Barnum and Trout Lake plutons north of Thunder Bay. The sandstone property on Vert Island should be considered as a potential producing site. The author has received numerous inquiries about red sandstone both for new construction and for restoration work. La Grange Island in Nipigon Bay which is Crown land should also be examined as a source of red sandstone. Good quality red sandstone is in short supply.

"Marble" (limestone) has been described at a number of localities in the Black Sturgeon River area by Coates (1972). Some of these sites may warrant investigation as sources of decorative stone.

QUATERNARY GEOLOGY by F.J. Kristjansson

MANITOUWADGE AREA

A program designed to provide detailed surficial geological mapping at a scale of 1:50 000 of the Manitouwadge map area (42F4) has been completed. A phased approach was used to organize the project (i.e., Step I: Data Collection and Review, Step II: Field Reconnaissance (83 and 85 field seasons), and Step III: Map Production). The study began with a literature search and review. Conventional aerial photography at 1 inch to 1 mile and 1 inch to 1/4 mile scales was obtained. A preliminary aerial photograph interpretation was conducted. During the second phase of the project, which required two field seasons to complete, all preliminary interpretation was subjected to a program of field verification. The surficial geology of the west one-half of the map sheet was documented during the 1983 field season. The east one-half of the map sheet was mapped during the 1985 field season. The objective was to obtain as many points of ground truth in the study area as possible. Navigable roads were traversed by vehicle, and all sand and gravel pits, and borrow pits, were visited. Detailed ground truth of the geomorphology and surficial geology of the Manitouwadge area was obtained. A preliminary map depicting the Quaternary Geology of the Manitouwadge area has been prepared.

GEOLOGICAL RESEARCH IN THE NORTH CENTRAL REGION

ONTARIO GEOLOGICAL SURVEY ACTIVITIES

Details of research carried out by the Ontario Geological Survey are given in Wood *et al.* (1985). A summary of these programs is listed below:

T.L. Muir, A Map of Hemlo Deposit; G.M. Siragusa, Geology of the Black River Area; B. Geddes, Quaternary Mapping in the Hemlo Area; M.W. Carter, Geology of Conmee, Forbes and a Portion of the Dawson Road Lots; L. Chorlton and G.H. Brown, Geological Setting of Gold Mineralization at Shebandowan; S.J. Buck and H.R. Williams, The Nature of the Quetico-Wabigoon Contact Near Longlac; R. Sutcliffe, Geology of the Lake des Iles Area; J. Macdonald, Platinum-Palladium Mineralization of the Lac des Iles Area.

Table 4.7 lists maps and reports published during the year by the Ontario Geological Survey, Ontario Ministry of Northern Development and Mines, Toronto.

RESEARCH BY OTHER ORGANIZATIONS

Geological Survey of Canada

Activity by the Geological Survey of Canada included a regional geological compilation of Northwestern Ontario, emphasizing the granitic terrains by J. Percival. I. Cameron and K. Hattori are carrying out a number of isotope geology studies in the Hemlo area. P. Harris is carrying out detailed mineralogical studies in the Hemlo area.

B.Sc. Theses Completed in 1985

Alford, C.

Structure Analysis of Multiply Deformed Metasedimentary and Metavolcanic Strata in the Mawn Lake Area.

Gliddon, D.J.

Chemical Sedimentation and Depositional Environment of Barite and Associated Chemical and Clastic Sediments Near Hemlo, Ontario.

Harvey, P.G.

Lateral Secretion at the Rabbit Mountain Mine, Mainland Belt Silver Region, Thunder Bay District.

Martin, A.

Structural Analysis of Multiply Deformed Metasedimentary and Metavolcanic Strata in the Max Lake Area.

O'Brien, M.

Volcanics of the Poplar Lodge Area, Beardmore, Ontario.

Schuster, R.A.

Depositional Setting and Landform Evolution Depicted by Pleistocene to Recent Sediments North of Thunder Bay, Ontario.

Scott, B.M.

Alteration Surrounding Gold-Bearing Quartz-Carbonate Veins in Clastic Hosted Banded Iron Formation, Jellicoe-Geraldton Area, Ontario.

Sinclair, T.J.

Alteration Surrounding Gold-Bearing Quartz-Carbonate Veins in Volcanic Hosted Banded Iron Formation, Jellicoe, Ontario.

Simunovic, A.

Strain Analysis of Clastic Sedimentary Rocks and Pillow Lavas from the Wabigoon Sub-province in the Vicinity of Max Lake.

M.Sc. Theses (in progress)

Devaney, J.R.

Depositional Environment of Coarse Clastics in the Archean Beardmore-Geraldton Sedimentary Belt, Ontario.

Jennings, E.A.

Fluid Geothermometry of Silver Vein Deposits of the Thunder Bay Area, Northwestern Ontario.

Laderoute, D.

Petrology and Geochemistry of Lamprophyres and Other Dike Rocks from the Coldwell Complex.

Lukosius-Sander, Y.

Geology of Centre 3, Coldwell Complex.

MacTavish, A.D.

Geology and Petrochemistry of Quetico Mafic-Ultramafic Intrusions.

Riley, B.

Paint Lake Fault Geology, Brock University.

Sarvais, P.

Anisotropism in the Quetico Fault.

Schnieders, B.R.

Geology, Structure and Depositional Environment of Chemical and Clastic Sediments in the Steel River Area, Terrace Bay, Ontario.

Thomson, K.

Depositional Setting of Chemical and Clastic Sediments in the Greenstone Belt Between Marathon and White River.

M.Sc. Theses Completed

Brown, G.H.

Structure and Stratigraphy of Timiskaming Rocks in the Shebandowan-Shabaqua-Finmark-Lappe Areas.

Zayachkivsky, B.

Geochemistry and Mineralogy of Rare-Element Pegmatites in the Georgia Lake Area, Northwestern, Ontario.

Other Staff Research Activities

Borradaile, G.J.

(1) Structure of the Margins of the Quetico and Wabigoon "Belts", especially between Atikokan and Mine Centre.

(2) Structure and Strain Analysis of Greenstone Wedges in the Wabigoon Sub-province.

(3) Strain and Magnetic Anisotropy of Archean Metasedimentary Rocks, Especially Seine River Sequence.

(4) Rock Mechanics Testing and Seismic Anisotrophy of Plutonic Archean Rocks to 3 kb and 300°C With/Without Pore Fluid Pressures.

Fralick, P.W.

The Depositional Environment of Oxide and Sulfide Facies Algoman Banded Iron Formation.

Hale, C.J., and Steward, J.D.

Petrography and Paleomagmatism of the Gunflint Formation with Reference to Paleo-Indian Artifacts.

Kehlenbeck, M.M.

(1) Character of the Quetico-Wabigoon Boundary Zone in the Beardmore-Geraldton-Longlac Area.

(2) Deformation of Non-Spherical Objects in Rocks from the Jellicoe-Geraldton Area.

(3) Progressive Deformation and Fold Evolution in Metasedimentary Rocks of the Quetico-Wabigoon Boundary Zone.

(4) Progressive Inhomogeneous Simple Shear and Uniform Homogeneous Strain as Related to Folds in the Beardmore-Geraldton Boundary Zone.

Kissin, S.A.

Diagenetic Reactions in the Gunflint Formation.

Liquid Immiscibility in the Logan Diabase Sills, Northwestern Ontario.

Mitchell, R.H.

Petrology and Geochemistry of the Coldwell Complex.

Other Universities

Bajc, A.

History and Development of the Pro-Glacial Lake Deposits in the Black River Area, University of Waterloo.

Barnett, B.

Geology of the Williams Deposit, Hemlo, Ontario, Ph.D. Thesis, University of Western Ontario.

Bree, D.G.

Investigation Into the Nature of Gold in Humus and its Significance to Geochemical Exploration, Hemlo, Ontario, Queen's University.

Burke, R.

5. North Clay Belt and Lowland Resident Geologist Area, Northern Region

W.O. Mackasey[1] and M.C. Digby[2]

[1]Resident Geologist, Ontario Ministry of Northern Development and Mines, Timmins

[2]Contract Geologist, Ontario Ministry of Northern Development and Mines, Timmins

INTRODUCTION

A new Resident Geologist District was formed in April 1985. This area is composed of two parts. The first part consists of the North Clay Belt, and extends from the Quebec Border and Detour Lake west to include Cochrane, Kapuskasing, and Hearst. The second part consists of the James Bay and Hudson Bay Lowlands.

The office is staffed by W.O. Mackasey, Resident Geologist, and M.C. Digby, Contract Geologist. Office quarters are shared with the Timmins Resident Geologist, and support services are provided by D. Draper, Data Geologist, and Diane Egerland, Secretary.

Much of the field season was spent gaining familiarity with the geology, mineral deposits, and accessibility of the area. Up-to-date road maps and logistical information were provided by the Cochrane, Kapuskasing, and Hearst Ministry of Natural Resources District Offices.

CLAIM STAKING ACTIVITY

A total of 778 claims were staked in the North Clay Belt and Lowland Area from January 1, 1985. to December 1985. As of December 1985, 6846 active claims are held in the area. Areas of active claim staking in 1985 include the Detour Lake area and McCowan, Fergus, and Ecclestone Townships.

EXPLORATORY LICENCES OF OCCUPATION

In the past few years, three companies have held exploratory licences of occupation in the Moose River Basin.

During 1985, two of the licences expired. The Douglas-Taylor Joint Venture licence, which had covered an area of 10 400 acres in the Kipling Township area, was not renewed. The licence granted to B.P. Exploration Canada Limited, covering 7200 acres, expired September 1, 1985.

The Onexco Minerals Limited exploratory licence was maintained at 150 000 acres during 1985.

ONTARIO MINERAL EXPLORATION PROGRAM (OMEP)

As of November 12, 1985, seven Ontario Mineral Exploration Program grants have been awarded to assist exploration programs in the North Clay Belt and Lowland area during 1985. A total of $794 846 has been committed as OMEP's share of exploration costs. Planned exploration expenditures for the seven grants amounts to $3 179 381.

DRILL CORE LIBRARY PROGRAM

Drill core for the area is stored in the Porcupine Mining Division Drill Core Library in Timmins. Over 13 252 m of core representing 23 734 m of drilling is currently available for public inspection. Table 5.1 and Figures 5.1 and 5.2 give details on the core collection.

Core from some of the deep oil and gas test wells drilled in the Lowland area is currently stored in the Ministry of Natural Resources, London, Ontario, core storage facility.

PROSPECTING CLASSES

Staff from the Timmins office presented ten-hour basic introductory prospecting courses during March and April in Kapuskasing and Hearst. Emphasis was on rock and mineral identification, prospecting techniques, and claim staking.

The course in Kapuskasing was sponsored by Northern College and 25 participants were enrolled. Thirty-one participants attended the classes in Hearst. The course in this locality had been arranged by the Hearst Ministry of Natural Resources District Office.

ONTARIO GEOLOGICAL SURVEY ACTIVITIES

In 1985, there were three projects undertaken by the Ontario Geological Survey in the North Clay Belt and Lowland Resident Geologist area.

ENGINEERING AND TERRAIN GEOLOGY SECTION

A 321 m borehole was completed during March 1985, in Morrow Township to gain information on the stratigraphy of the eastern part of the Moose River Basin. The hole was collared approximately 5 km west of the Onakawana railway siding.

The drilling was able to confirm that the Long Rapids Formation is anomalously thick in the Onakawana area. A 1.5 m lignite seam was intersected at the base of the Mattagami Formation (Sanderson and Telford 1985).

The core from this hole is stored at the Drill Core Library in Timmins.

MINERAL DEPOSITS SECTION

A second field season was completed by Soussan Marmont on the study of the Detour Lake Mine Area. This included underground mapping and mapping of surface geology beyond the mine site. Detailed mapping of the underground workings provided new information on the geological features of the gold deposit. Late Archean deformation associated with gold mineralization is described by Marmont (1985).

PRECAMBRIAN GEOLOGY SECTION

A 1075 km^2 area was mapped south of Hearst and Kapuskasing during the 1985 field season. The map area included Caithness, Rykert, Fergus, and Ecclestone Townships and parts of Scholfield, Pelletier, Doherty, Abbott, Opazatika, and Bourinot Townships.

The project better defined the volcanic stratigraphy of the area and revealed the presence of a felsic pyroclastic unit (Berger 1985). Table 5.2 lists the maps and reports, pertaining to the North Clay Belt and Lowland, that were published by the Ontario Geological Survey during 1985.

ONTARIO GEOSCIENCE RESEARCH GRANT PROGRAM

During 1985, two research projects were carried out in the Resident Geologist's area.

A report on Grant 134, entitled "Geochemistry and Petrography of the Mattagami Formation Lignites (Northern Ontario)", was prepared by Winder *et al.* (1985). One conclusion reported in this study is the extremely clean nature (low metal content) of the Moose River Basin coals.

Field work was continued in 1985 in the Williams Island area of the Abitibi River as part of Research Grant 216. This is a study of the Long Rapids Formation shale which is considered a possible source of shale oil. A report on the project, entitled "Sedimentology of the Long Rapids Formation, Preliminary Results", has been prepared by Bezys and Risk (1985).

ACTIVITIES OF OTHER AGENCIES

In addition to the work being done by the University of Western Ontario and McMaster University under the Ontario Research Program (Winder *et al.* 1985; Bezys and Risk 1985), four other projects were reported on in 1985.

A Laurentian University thesis on the sedimentology of the Mattagami Formation (Try 1984) was received by the Resident Geologist office this year.

Work by the Geological Survey of Canada on the Kapuskasing Structure was reported by Percival (1985) and Woods (1985).

An inventory of Industrial Mineral Resources of the North Clay Belt was prepared by Guillet (1985).

MINING AND EXPLORATION ACTIVITY

Lists of the assessment work done and exploration activity, pertaining to the North Clay Belt and Lowland, are found in Tables 5.3 and 5.4.

METALS

Partridge River Area

Noranda Exploration Company Limited filed reports of work in 1985 for work done in 1983/84. Ground electromagnetic and magnetic surveys for a number of localities in the Partridge River Area were completed. This work was in conjunction with a geological mapping program in a large area of volcanic rocks north of Kesagami Lake not presently shown on government geological maps.

McCowan Township Area

A large number of claims have been staked around the patented ground commonly referred to as the Filion Gold Occurrence in McCowan Township. Assessment work reports for ground magnetometer and VLF surveys of the Romex Resources Incorporated/ Omab Enterprises Limited joint venture were received this year.

Fushumi-Burstall Townships Volcanic Belt

Noranda Exploration Company Limited has completed horizontal loop electromagnetic and magnetic surveys in several locations of this mainly drift-covered volcanic belt stretching from Auden Township northeast to Burstall Township. This company had previously flown airborne geophysical surveys in the area. Assessment work reports, completed by the same company for geophysical surveys in Auden and Burstall Townships, were received in 1985.

Foch-Lessard Townships Area

Reports of work have been filed by Noranda Exploration Company Limited and R.B. Murray for airborne electromagnetic and magnetic surveys in the area. These surveys cover an area west of Hornepayne covering approximately 1200 mining claims.

Caithness-Fergus Townships Volcanic Belt

Prospecting for gold was under way in this area during 1985. A number of mining claims have since been staked across a six-township stretch. A geological study of this area, by the Ontario Geological Survey, is in progress (Berger 1985).

Bayfield Township Area

Teck Exploration Limited submitted assessment work reports in 1985 for magnetic and electromagnetic surveys for the mainly drift-covered area south of Hornepayne.

Casselman-Fenton Townships Volcanic Belt

Prospector Joseph Arsenault continued prospecting for gold in the Slack Township property in 1985. Groups of mining claims were recently staked in Staples and Casselman Townships.

Detour Lake Area

The Detour Lake Mine, which is a joint venture between Amoco Canada Petroleum Limited and Campbell Red Lake Mines Limited, completed its second year of production in 1985.

In the past year, steps have been taken to overcome grade and milling problems encountered in 1984. As part of the plan, the ore reserves were revised to 10.9 million tons of 0.128 ounce gold per ton, down from the original 30.2 million tons of 0.113 ounce gold per ton (The Northern Miner, January 31, 1985).

The open pit mining operation will be continued until the third quarter of 1986. Shaft sinking was completed this year to a final depth of 612 m. Lateral development work will commence early in 1986.

Following evaluation, a decision to go ahead with production will be made in the second half of 1986. Underground production would not start up until the first quarter of 1988.

The mill will be kept operating during the last quarter of 1986 using material from a low grade stockpile. Studies are currently under way to keep the mill in continuous operation throughout 1987.

In November, a pilot hole drilled from the 11th level (550 m below surface) confirmed the presence of the main zone at that level.

Production at the present time is 2200 tonnes per day. Millheads to date are slightly under the projected grade for 1985. There are presently 248 persons employed at the mine site (Detour Lake Mine, personal communication, 1985).

The Ontario Geological Survey finished a second field season studying the Detour Lake mine site area (Marmont 1985).

A variety of ground geophysical surveys (I.P., E.M., magnetic) were completed and reported on for the Detour Lake area by Ingamar Resources Limited, Noranda Exploration Company Limited, Ormont Explorations Limited, and Westmin Resources Limited. Petromet Resources Limited submitted a report of work for geochemical studies.

Westmin Resources Limited submitted assessment reports for nine drillholes totaling 1539.2 m that were drilled in the area in 1984 and 1985.

Dome Exploration Limited completed 11 diamond-drill holes in the Lower Detour Lake area as part of its ongoing program to gain geological information in the Detour Lake Mine area. Twenty holes totaling 3100 m were drilled west of the Detour Lake road in the Kesagami River and Marquis Lake map areas. Nothing of economic interest was encountered in this area (Dome Exploration Limited, personal communication, 1985).

Valentine Township

B.P. Resources Canada Limited submitted a drill log for a hole completed in Valentine Township in 1982. The hole which was part of the company's diamond exploration program intersected 47 m of "kimberlitic" breccia.

Oba Volcanic Belt

Falconbridge Limited continued work on its Hawkins-Walls Townships gold properties. Assessment work reports were submitted in 1985 for 27 diamond-drill holes completed in 1984 and 1985, as well as geo-

logical mapping and geophysical and geochemical surveys completed in 1984. Parts of these properties have been under option from L. Gervais and D. Bremner.

INDUSTRIAL MINERALS

Sherritt Gordon-Campbell Resources Joint Venture

Cargill Township Phosphate and Vermiculite Deposit The main geological feature of this area is the Cargill carbonatite complex. The phosphate is present as the mineral apatite which forms a residuum deposit above the carbonatite zone. The vermiculite occurs in a leached zone along the contact between carbonatite and pyroxenite.

In 1985, a 100-ton per day mill and assay lab were constructed on the property for the purposes of conducting a pilot mill test for the Cargill phosphate. The mill, which was constructed for warm weather operation, contains a crusher, screen, rod mill, attrition-scruber, separator, cyclonic flotation unit, and disk filter.

A 6000-ton sample from the open pit was put through the mill for mechanical and reagent testing. An end product ranging between 36% to 38% P_2O_5 was achieved. No further work is planned until new phosphate markets develop in Ontario (Sherritt Gordon Mines Limited, personal communication, 1985).

The Kapuskasing Experimental Farm of Agriculture Canada's Research Branch has initiated a project using untreated phosphate rock from the Cargill Township phosphate deposit as a slow release fertilizer. Preliminary tests show that soluble phosphate can be released in compost mixtures. Greenhouse tests are planned for the Kapuskasing facility early in 1986 (Agriculture Canada, personal communication, 1985).

Bench tests on the vermiculite from the Cargill Township property show it to be of high quality. Field tests to date have not been able to substantiate that an economic tonnage of vermiculite exists (Sherritt Gordon Mines Limited, personal communication, 1985).

Martison Lake Phosphate-Niobium Deposit This deposit which lies 100 km north of Hearst is geologically similar to the Cargill carbonatite complex. Guillet (1985) indicated that the Martison deposit contains an estimated 140 million tonnes of 20% P_2O_5 and 0.35% Nb_2O_5. In 1985, assessment work reports were submitted for drill testing and beneficiation studies.

Carlson Mines Limited

In August 1985, Carlson Mines Limited completed three exploration sonic drill holes and an engineering feasibility study on its Kipling Township kaolin-silica sand option. The company is currently stripping overburden and plans to collect a 500 ton bulk sample of kaolin and silica sand. The sample will be shipped to the Ontario Research Foundation for metallurgical testing.

North Clay Belt Industrial Minerals Conference

The North Clay Belt Development Association held a two-day conference in October dealing with the potential of Industrial Minerals in the area. As part of the conference, ceramic, glass, and alabaster crafts made from local materials were on display. Results of firing tests demonstrating the high quality of various clays of the region were also presented.

Three studies were commissioned as part of the conference. The first is an inventory of Industrial Mineral Resources of the North Clay Belt (Guillet 1985). An Industrial Minerals Business Opportunities investigation is being conducted by the firm Currie, Coopers and Lybrand. Peter Bannard Associates have undertaken a study of markets for crafts from Northeastern Ontario.

FIELD AND PROPERTY VISITS

The field and property visits for 1985 are listed in Table 5.5.

HIAWATHA GOLD MINE AREA

During the visit to the former Hiawatha Gold Mine in Lizar Township, an examination was made of the northeast-trending granitic dike. Gold mineralization appears to be spatially associated with this dike which is 400 feet wide, vertically dipping, and cuts pillowed mafic and mafic metavolcanics. Weathered exposures along the shore line of Kabinakagami Lake suggest that it is a quartz-feldspar porphyry. This body may be related to subvolcanic intrusive activity rather than later granitic intrusive activity as shown on present geological maps.

OBA VOLCANIC BELT

In the Oba area, gold mineralization is related to fine-grained felsic tuffaceous zones within mafic metavolcanic flows. A sample of the felsic tuff collected from a trench by the Resident Geologist and analyzed by the Geoscience Laboratories, Ontario Geological Survey, Toronto, was found to contain 480 ppm barium.

SLACK TOWNSHIP

In Slack Township, zones of epidotization, hematitization, and carbonatization were found in some of the mafic metavolcanic exposures. A highly folded chert-magnetite iron formation with pyrite and pyrrhotite replacement zones occurs on the J. Arsenault property. A small piece of pyritic iron formation float located by the Resident Geologist near the end of an old logging road northeast of the Arsenault property, was analyzed by the Geoscience Laboratories, Ontario Geological Survey, Toronto, and found to contain 0.01 ounce gold per ton and 0.52 ounce silver per ton.

PARTRIDGE RIVER VOLCANIC BELT (SOUTH)

A field visit was made to a volcanic belt just south of the Partridge River Volcanic Belt. Geological maps in the Glaister Lake and the West of Glaister Lake areas of the volcanic sequence have recently been submitted (1984) as assessment work reports.

TABLE 5.5 . 1985 FIELD AND PROPERTY VISITS

1.	Hiawatha Gold Mine Area
2.	Hornepayne Area Granitic Terrain
3.	Oba Volcanic Belt
4.	Caithness Township Volcanic Terrain
5.	Cargill Phosphate Deposit
6.	Buchan Township Glacial Formations
7.	J. Arsenault Property, Slack Township
8.	Kipling Township Kaolin Deposits
9.	Cheepash River Gypsum Deposits
10.	Moose River Gypsum Deposits
11.	Argor Niobium Deposit
12.	Partridge River Volcanic Belt South
13.	Kenogami River Formation, Low Shoal Island
14.	Detour Lake Gold Mine
15.	Long Rapids Formation, Abitibi River
16.	Mattagami River Siderite Deposits

Thick sequences of pillowed mafic metavolcanics with interbedded felsic tuffs and flows are well exposed in areas of recent forest fires. Primary volcanic features are well preserved. Metamorphic grade is believed to be in the upper greenschist-lower amphibolite range. The area is presently shown on government maps as migmatite.

MOOSE RIVER BASIN

During the course of the field season, boulders of mafic and amygdaloidal volcanic rocks, not unlike the Keweenawan volcanic rocks of the Lake Superior region, were located along the banks of the Moose and Abitibi Rivers in the Moose River Basin. Some of these volcanic boulders are angular and do not appear to have been moved far from their bedrock source.

A drillhole in Kilmer Township, collared in 1943, intersected 41.4 m of "Late Precambrian" amygdaloidal and serpentinized basalt and argillite lying beneath 22.9 m of overburden and overlying granitic basement (Satterly 1953). It is possible that the volcanic boulders, which were found some 70 km downstream from Kilmer Township, represent eroded remnants of a hidden Proterozoic volcanic sequence.

RECOMMENDATIONS FOR PROSPECTING

OBA VOLCANIC BELT

Gold appears to be related to fine-grained felsic tuffaceous rocks interbedded with mafic metavolcanics in Hawkins and Walls Townships. Felsic tuffaceous zones should be given close examination when prospecting for gold in this area. The presence of trace amounts of barium in these rocks may possibly serve as a pathfinder for gold exploration in this belt.

CAITHNESS-FERGUS TOWNSHIPS VOLCANIC BELT

The Precambrian geology of this area has been recently mapped by the Ontario Geological Survey (Berger 1985). In his preliminary report of the area, Berger (1985) makes a number of suggestions for prospecting in the area. Three of these recommendations include, a felsic pyroclastic unit in Pelletier and Doherty Townships which may have potential for base and precious metal mineralization, a shear zone in the vicinity of the Rufus Lake Dam which has produced an area of quartz-muscovite schist that should be prospected for precious metals, and a 250 m thick section of gossan with pyrite and graphite which was mapped in Pelletier Township.

SLACK TOWNSHIP

The gold-bearing float assaying 0.01 ounce gold per ton and 0.54 ounce silver per ton, found in northeast Slack Township, may be from a local source. Prospecting in the area is warranted.

PARTRIDGE RIVER VOLCANIC BELT (SOUTH)

The recently documented volcanic terrain of the Partridge River-Kesagami Lake area may have potential for base and precious metals.

INDUSTRIAL MINERALS

The long term growth projection for many industrial minerals should be considered when formulating exploration plans. The inventory recently compiled by Guillet (1985) covering the industrial mineral potential of the North Clay Belt serves as a good reference for the area.

RESIDENT GEOLOGIST STAFF ACTIVITIES

Staff at the Timmins Resident Geologist's Office includes: M.S. Paradis, Regional Mineral Resources Coordinator, L.E. Luhta, Resident Geologist, P.J. Sangster, Resource Geologist, and D.C. Egerland, Secretary. C.D. Hamblin continued as Drill Core Librarian under a contract administered by the Timmins District Office, Ontario Ministry of Natural Resources. During 1985, D.M. Draper was hired on a contract basis as Data Geologist and J.C. Ireland held the contract position of Economic Geologist for the Swayze Belt. Additional temporary staff hired under Experience '85, Ontario Youth Corps, and Special Employment programs included: P. Blomberg; L. Perron; D. Cholette and K. Marinacci.

The level of exploration activity remained relatively high in spite of the depressed price of gold and base metals during 1985. The staff spent considerable time in consultative duties with over 1800 office consultations recorded. Emphasis was placed on examining and reporting on properties currently being explored and/or developed. Other staff activities included providing geological background information to land use plans; conducting geological field trips; organizing seminars and presenting lectures on local geology. In addition, staff from the Timmins Resident Geologist Office designed and presented two short Prospecting Courses to local groups in 1985.

In the Timmins Resident Geologist's area, there are presently: eight producing gold mines; one producing base-metal mine; and one producing industrial mineral mine. There are seven advance gold evaluation and development projects being carried out and one advanced industrial mineral development project. In 1985, there were 28 major and 78 junior mining exploration companies active in the Timmins area and 35 individuals conducted exploration projects.

CLAIM STAKING ACTIVITY

From December 1984 to the end of November 1985, 5264 claims were recorded in the Porcupine Mining Division. Of this total, 4486 claims were recorded in the Timmins Resident Geologist area. There are at present 21 793 active claims in the Porcupine Mining Division as compared to 26 793 active claims at this time last year. These active claims represent approximately 871 720 acres (352 772 ha) of ground being explored in the entire Mining division. In the Timmins Resident Geologist area, there are 14 947 active claims representing 597 880 acres (241 953 ha) of ground under exploration. Additional programs on patented ground are not included in this acreage.

Intensive staking activity centred on an area within a four-township radius around Timmins and in Rollo, Raney, Marion, Mallard, Benton, and Osway Townships in the Swayze Belt area. Increased staking was noted in Neill Township in the southwestern corner of the Resident Geologist area.

Active stakers in the Timmins Resident Geologist area included: H. Gonzalez; Mid-Canada Exploration; and Ingamar Exploration.

CORE LIBRARY PROGRAM

From January to the end of November 1985, a total of 441 representatives of government and industry made use of the core library facilities. During the same time period, 32 442 m of drill core and samples representing an additional 4900 m of core were collected. The core library now contains approximately 126 035 m of drill core of which 111 300 m has been catalogued and entered onto a computer indexing system. During 1985, drill core was received from the following sources:

Canamax Resources Incorporated
Chevron Resources Canada Limited
Cleyo Resources Incorporated
Comstate Resources Limited
J. Croxall
Diepdaume Mines Limited
Dominion Gulf Company
Esso Minerals Canada
Ingamar Explorations
Kenty Resources Limited
Kerr Addison Mines Limited
Labrador Mining and Exploration Company Limited
Lacana Mining Corporation
Robert S. Middleton Exploration Services Incorporated
Newmont Exploration of Canada Limited
Noranda Exploration Company Limited
Pamour Porcupine Mines Limited
Pominex Limited
Shiningtree Gold Resources Incorporated
Utah Mines Limited
Westmin Resources Limited

OPERATING MINES

BASE METALS

Kidd Creek

Although the complete 1985 figures are unavailable at the time of writing, the projected production for 1985 at the Kidd Creek Mines Limited base-metal mine in Kidd Township is 4 541 000 tonnes. In 1984, the company produced and processed 4 513 000 tonnes of ore from which 211 000 tonnes of zinc con-

centrates were produced for sale. The company also produced 122 000 tonnes of zinc which was refined at the Kidd Creek metallurgical site in Hoyle Township. Copper concentrates produced for sale totaled 30 000 tonnes. Copper metal produced at Kidd Creek's metallurgical site was 68 000 tonnes. From the remaining concentrate, 37 000 tons of copper metal were produced on a toll basis elsewhere in Canada. Total silver recoverable in 1984 was 271 000 kg. In addition, 600 tonnes of cadmium; 26 000 tonnes of lead silver concentrates, and 414 000 tonnes of sulphuric acid were produced.

Seventy-six percent of production at the Kidd Creek Mine came from the Number One Mine with most of the ore coming from above the 2000-foot (610 m) level.

Most of the deposit is mined out above the 1200-foot (366 m) level. At the Number Two Mine, production took place between the 2600 (792 m) and 4000-foot (1219 m) levels. The bottom level at the Number One Mine is 2400 feet (732 m). The lowest level being developed presently at the Number Two Mine is the 4000-foot (1219 m) level.

Proven and probable reserves to the end of 1984 totaled 67.6 million tonnes containing 3.2% copper, 4.9% zinc, and 67 grams silver per tonne.

It is interesting to note that in 1985, total mined tonnage equalled the proven and probable ore reserve remaining in the mine. This total, mined ore plus ore remaining, represents 131.6 million tonnes down to 4800 feet (1463 m) below surface.

In 1985, underground development at the Number One Mine totaled 9714 m (6402 m of lateral and 3312 m of vertical development). At the Number Two Mine, development totaled 5993 m (including 4610 m of lateral and 1420 m of vertical development). This compares with the 1984 figures of 11 200 m at the Number One Mine and 4575 m at the Number Two Mine. Underground diamond drilling totaled 21 610 m of which 50% was ore delineation drilling. The remaining 50% was considered primary ore definition and exploration drilling. The total underground drilling for 1984 was 22 400 m. Delineation drilling at the Number One Mine is 90% complete. Primary ore definition drilling is beginning on the 4600-foot (1402 m) level. Surface exploration drilling at the Kidd Creek Mine site totaled 1376 m in 1985. This compares to 3000 m of surface drilling done in 1984.

Kidd Creek Mines Limited has started a $66 million expansion of its metallurgical facilities to be completed in 1988. This expansion will enable the company to smelt and refine more of its concentrate production, thus reducing unit costs and increasing net annual revenue.

The number of persons employed in mining and metallurgy at Kidd Creek Mines Limited in Timmins in 1985 was 2713. The 1984 figure was 2808 (Kidd Creek Mines Limited, personal communication, 1985).

PRECIOUS METALS

Dome Mines Limited

In 1985, the Dome Mine in South Porcupine produced gold ore at a rate of 3000 tons (2721 tonnes) per day for first full year.

The Dome's $92 million expansion to increase production from 2000 tons (1814 t) to 3000 tons (2721 t) per day was completed in 1984. Although the 1985 production figures are unavailable at the time of writing, it is expected that the Dome will mine and mill 1 050 000 tons (952 544 t) for the year. In 1984, 860 000 tons (790 179 t) of ore were milled, producing 118 472 ounces (3 684 891 g) of gold. Mill recovery was 97%. The average mill head grade was 0.142 ounce gold per ton (4.85 g/t). Ore sources by mining method are 57% longhole, 33% cut and fill, and 7% from development.

Ore reserves at the end of 1984 were calculated to be 2 629 000 tons (2 384 989 t) grading 0.170 ounce (5.85 g/t) gold per ton. Over 50% of the mill feed is still extracted above the 2000-foot (610 m) level. The lowest working level at the Dome is 4000 feet (1220 m) below surface with the main ore structures being traced below this level.

In 1985, 20 710 feet (6312 m) of lateral development (crosscuts, drifts, and sill drifts) and 1928 feet (588 m) of raising was done. This is lower than the 1984 figures of 21 550 feet (6568 m) and 2720 feet (829 m), respectively. In 1985, underground diamond drilling totaled 53 800 feet (16 398 m) of which exploratory drilling totaling 5850 feet (1783 m) was done in the new Eight Shaft area. This is a little lower than the previous year's total of 54 500 feet (16 612 m) of underground drilling.

At present, two long exploration drives are advancing from the Number Eight Shaft along the 30 and 32 levels (4200 feet (1280 m) and 4500 feet (1372 m) below surface) toward the old Number 7 (internal) Shaft area. This shaft was abandoned in 1971 when exploration was concentrated on finding gold values between 0.20 and 0.25 ounce per ton (6.9 and 8.6 g/t). Now grades of 0.15 to 0.175 ounces (5.1 to 6.0 g/t) are considered to be ore grade.

A total of 776 people were employed by Dome Mines Limited at their operations in South Porcupine during 1985 (Dome Mines Limited, personal communication, 1985).

Owl Creek

At the Kidd Creek Mines Limited Owl Creek open pit gold mine, production to the end of 1985 is anticipated to be 280 000 tonnes. By the end of 1985, 260 000 tonnes of gold ore will have been processed at the Pamour Porcupine Mines Limited gold mill on a custom basis. A total of 20 000 tonnes has been stockpiled for processing at Kidd Creek's copper smelter after the crushing plant has been upgraded. Average mill head grade will be 3.9 grams of gold per tonne.

At present, the fifth bench is the lowest mining bench with production coming from the third and fourth benches as well. The last full bench will be the ninth with limited production coming from the tenth, 100 m below surface.

Reserves at the Owl Creek Mine to the end of 1985 are 725 000 tonnes at 4.1 grams gold per tonne.

Hoyle Pond

At the end of April 1985, Kidd Creek Mines Limited made a decision to bring the Hoyle Pond gold mine into production. Underground evaluation of the deposit, located just east of Kidd Creek's Owl Creek mine in Hoyle Township, began in the summer of 1983. A decline was driven from surface, eastward. Presently, the decline is down to the third level, 166 m below surface. The fourth level, 211 m below surface, will be reached in 1986. To obtain mill feed, three sublevels were driven above the second level, on ore, at 6.5 m intervals. A ramp is presently being driven to the fourth. Total lateral development at Hoyle Pond in 1985 was 2197 m.

Milling of Hoyle Pond gold ore began November 9, 1984, at a rate of 300 tonnes per day, five days a week using the Asarco Exploration mill in Macklem Township. The mill was previously used by Asarco Exploration Company of Canada Limited to test mill material from the Aquarius gold deposit. Mining was postponed indefinitely at the Aquarius mine and the mill was made available to Kidd Creek Mines Limited on a custom basis.

Total production for 1985 at Hoyle Pond was 64 000 tonnes at a grade of 14.43 grams of gold per tonne (70 550 tons at 0.42 ounce gold per ton). Mill recovery was 96%. All production was from development as no stopes have yet been put into production. Cut and fill mining is planned for Hoyle Pond with copper slag to be used as fill. A mining method above the second level where the subdrifting has taken place "to obtain quick muck" has yet to be decided on. Sublevel retreat followed rapidly by filling is one of the options being considered.

To bring the Hoyle Pond mine into production, $14.4 million has been budgeted. This includes the construction of a gold mill at Kidd Creek metallurgical site and upgrading the crushing plant. New mine offices and a dry are being built.

Air, water, and power lines have been completed. The mill is designed for 300 tonnes per day, seven days a week but will be capable of handling 600 tonnes per day. Planned tonnage is 425 tonnes per day, five days per week. In 1986, 96 000 tonnes are to be mined and milled.

In August 1985, Kidd Creek Mines Limited made an agreement to acquire the rights to the Schumacher Estate property which lies to the west and along strike of the Hoyle Pond mine.

Present ore reserves at Hoyle Pond are 405 000 tonnes grading 15 grams gold per tonne. A total of 61 people are presently working at both Owl Creek and Hoyle Pond (Kidd Creek Mines Limited, personal communication, 1985).

Pamour Porcupine Mines Limited

At the time of writing, December 10, 1985, the complete 1985 production figures for Pamour Porcupine Mines Limited are unavailable. However, an estimated breakdown of 1985 production compared to 1984 production is shown in Table 6.3.

The average gold grade for the total 1985 production is expected to be the same as that in 1984.

Pamour Porcupine Mines Limited custom milled 260 000 tonnes of gold ore from the Kidd Creek Mines Limited Owl Creek open pit mine.

In 1985, Pamour Porcupine Mines Limited completed: 12 000 feet (3658 m) of stope preparation and development and 20 000 feet (6096 m) of diamond drilling at the Number One Mine; 2000 feet (610 m) of stope preparation and development and 8000 feet (2438 m) of diamond drilling at the Schumacher Division; 2700 feet (823 m) of stope preparation and development and 4000 feet (1219 m) of diamond drilling at the Ross Division. In 1985, Pamour rerouted a 1.5 km section of Highway 101 to the south of the Pamour townsite at the Number One Mine. The total cost of this move was $1 000 000. This work will enable the company to mine the new Number Three open pit located just to the south of the old Number One pit. An additional $1 500 000 was spent on pit preparation and on the purchase of new equipment for the project.

In October 1984, Pamour announced the closure of Pamour Number Three (underground); Timmins Property (underground); and the Schumacher Division (underground) due to poor economic conditions. The Schumacher Division was subsequently given a reprieve and continues to operate on a month to month basis. Pamour Porcupine Mines Limited is investigating the possibility of extracting ore from the walls of the previously mined shrinkage stopes on the Number Three vein system. Although these stopes produced high grade ore, narrow mining widths dictated by unstable ground conditions resulted in ore being left in the walls.

Sand fill will be removed from these stopes. Sloughing, possibly induced by blasting will then take place. Drawpoints will be driven at the bottom of the stopes where the ore would be mucked out. If successful, this scheme could extend the life of the mine considerably.

In August 1985, it was announced that Noranda Incorporated intended to sell its 48.7% share of Pamour Porcupine Mines Limited to Jimberlana Minerals N.L. of Australia for $10.00 per share or $34 130 170. The agreement is to take effect on December 27, 1985 (Pamour Porcupine Mines Limited, personal communication, December 10, 1985).

Renabie Mine

The Renabie Mine in Leeson Township continued gold production through 1985. Renabie Gold Mines Limited is owned by Barrick Resources Corporation (50%) and Royex Gold Mining Corporation. Royex is controlled by International Corona Resources Limited.

Most of the year's production from the Renabie Mine came from below the 3105-foot (946 m) level

(the bottom level in the mine) by a sublevel caving stoping method. Access to this ore was by a decline. Five sublevels at 30-foot (9.1 m) intervals below the 3105 level have been developed. Two small shrinkage stopes in the upper levels provided a minor amount of ore in early 1985.

Presently, the company is sinking a winze to access ore below 3105 since there is an economic depth limit to ramping. The winze is down to the 3600-foot (1097 m) level and is scheduled to be completed by the third quarter of 1986 reaching the 4300-foot (1310 m) level.

The mine is presently producing between 15 000 to 18 000 tons (13 608 to 16 330 tonnes) per month. Although the 1985 figures are unavailable at the time of writing, the mine is expected to produce 152 000 tons (137 892 tonnes) at a grade of 0.205 ounces (7.0 g) gold per year.

In 1985, drifting eastward on the 1400-foot (427 m) level was carried out towards the projected extension of the Nudulama gold zone. This zone is projected to plunge onto the Renabie property just below the 900-foot (274 m) level. A total of 1000 feet (305 m) of lateral development was done and 1000 feet of underground diamond drilling was completed. An additional 14 000 feet (4267 m) is planned from the 1400-foot level.

Surface exploration on the property by Renabie Gold Mines Limited consisted of geophysical and geochemical surveys and 25 diamond-drill holes totaling 7800 feet (2377 m) being drilled.

In 1985, 170 people were employed at the Renabie Gold Mine. (Renabie Gold Mines Limited, personal communication; personal observations, 1985).

Anglo Dominion Gold Exploration Limited

Anglo Dominion Gold Exploration Limited and Canreos Minerals (1980) Limited have signed an agreement with Kidd Creek Mines Limited to supply Kidd Creek's smelter in Timmins with gold-bearing flux. The agreement took effect on October 1, 1985, and calls for a total shipment of 160 000 tons (145 000 tonnes) over two years. Anglo Dominion Gold Exploration Limited and Canreos Minerals (1980) Limited will be paid for 87% of the contained gold. The silica content must be at least 77% silica. By the end of 1985, 18 000 tons (16 329 tonnes) will have been shipped with all of the ore coming from the Anglo Dominion property. Missibay Mining Limited, a private company, is the contractor for the project.

At the Anglo Dominion property in Leeson Township (former Nudulama Property) a 2400 ton (2177 tonnes) bulk sample grading 0.17 ounce gold per ton (5.8 g/t) was mined by open pit on the Number One Vein and shipped to the Kidd Creek smelter in January 1985. Open pit mining is presently being done on the west end of this vein.

At the east end of the vein, a decline, started in August 1985, has been driven down to the 150-foot (32 m) elevation. The first sublevel was driven along the vein for 500 feet (152 m), 75 feet (23 m) below surface. The vein zone here is from 7 to 30 feet (2.1 to 9.1 m) wide and slashing to the extremities of the ore was done on this sublevel. On the second sublevel, 300 feet (91 m) of drifting on vein was completed, 200 feet (61 m) below surface. It is planned to mine the Number One vein by vertical sublevel retreat to 500 feet (152.4 m) below surface. The top of the vein will be mined by open pit. All ore trucked to Kidd Creek in 1985 has come from this open pit and from the underground development.

On the Canreos property (the former Braminco property in Brackin Township), slashing of waste was done at the end of 1985 on the 21 vein open pit in preparation for mining a second 20-foot (6.1 m) bench. It was from this pit that a 2943 ton (2670 tonne) bulk sample grading 0.27 ounce gold per ton (9.2 g/t) and 77.9% silica was taken to the Noranda Horne Smelter in Quebec in February 1984. In November 1984, a 250 ton (227 tonne) sample also was taken from this pit and shipped to the Kidd Creek smelter. This sample was reported to assay 0.32 ounce gold per ton (11 g/t).

At the end of 1985, a decline was started at the south end of the 21 vein to access both the 21 vein and the Number 7 vein. 15 000 feet (4572 m) of diamond drilling was also done on the property to explore between the known veins in 1985.

Thirty people are employed by Missibay Mining Limited on both the Canreos and Anglo Dominion properties (Missibay Mining Limited, personal communication; personal observations; various Northern Miner articles, 1985).

INDUSTRIAL MINERALS

Steetley Talc Limited

In 1985, Steetley Talc Limited completed a $3.76 million expansion started in 1982. The expansion was funded partly by a grant for $940 000 from the government of Ontario through the Board of Industrial Leadership and Development (BILD). A series of small projects brought the total talc-producing capabilities at the company's facilities to 36 000 tons (32 658 tonnes) per year. An additional expansion, started in 1985 to bring the capacity to 60 000 tons (54 431 tonnes) per year, is scheduled to be completed by July 1986. Total cost for this is estimated to be $4.2 million. Steetley Talc Limited's market share is continuing to grow, even though competition is great.

Operations in 1985 included open pit mining and stockpiling of 120 000 tons (108 862 tonnes) of ore during the early part of the year. In 1985, 35 000 tons (31 751 tonnes) of beneficiated talc was produced compared to 30 000 tons (27 215 tonnes) in 1984 and 23 100 tons (20 956 tonnes) in 1983. The ore is mined and the talc concentrated at the mine site in Penhorwood Township. The concentrate is then trucked to the fine-grind plant in Timmins. The product is sold to the pulp and paper, paint, cosmetic, plastics, and rubber industries.

Steetley Talc Limited presently employs 50 people at its Timmins operations. This is the same number as in 1983 (Steetley Talc Limited, personal communication, 1984).

Extender Minerals Limited

In November 1984, Extender Minerals Limited began developing a barite deposit in the southwestern corner of Penhorwood Township. A new, 5 km access road north of the C.N.R. main line was constructed to access the property. To date, 1000 feet (305 m) of decline reaching a vertical depth of 150 feet (46 m) has been completed. The ramp will advance to reach the 180-foot (55 m) elevation by 1986. On the main vein structure, 50 feet (15 m) of drifting has been completed at the 100-foot (30 m) elevation. When the decline reaches a point underground just south of the open cut, a crosscut will be driven to the vein and a raise driven up along it into the open cut. Underground diamond drilling will be used to delineate the main vein at depth. Total expenditures to date are estimated to be just over $600 000.

The main barite vein strikes 050° and dips vertically. It is up to 7 feet (2.1 m) wide and occupies the sheared contact within a syenite. A narrow sheared serpentinized rock occurs along the south side of the vein. Quartz, barite, and fluorite stringers are adjacent to the vein. A second barite vein from 3 inches to 2 feet (7.6 cm to 0.61 m) in width located to the south of the main vein has been intersected by the ramp. This vein also occurs in sheared syenite.

During 1985, 130 tons (118 tonnes) of barite ore grading 50% was shipped to the Extender Minerals Limited mill in Matachewan. This ore was taken from a surface stockpile of underground development muck.

The appeal of this barite is its pure white colour which is in great demand.

Current plans are to produce 10 000 tons (9071 tonnes) of barite per year beginning in 1987. Total expenditures to date are estimated to be just over $600 000 for the project. Current barite reserves are estimated at 60 000 tons (54 431 tonnes).

Five people are presently employed at the project (Extender Minerals Limited, personal communication; personal observations, 1985).

PROPERTY EVALUATION AND DEVELOPMENT

CANAMAX RESOURCES INCORPORATED

Canamax Resources Incorporated as operator of a 50/50 joint venture with CSA Minerals Incorporated began a shaft sinking project at the Bell Creek gold deposit in Hoyle Township in late 1984. The objective of the underground program is to confirm gold grades estimated from drillhole data and examine mining conditions of the 'A' horizon of the North Zone.

In 1985, shaft sinking was completed to a depth of 280 m. However, a fire on July 30 destroyed the hoist building and electrical panel delaying the lateral development by three months. Stations will be cut at the 30, 60, 120, 180, and 240 m elevations. Crosscutting to the north zone, 285 m north of the shaft will be done on the 60 and 120 m levels. Results of this work will be evaluated and a decision will be made whether or not to go on with Phase II. This next program will include testing the zone on two additional levels and drifting and raising in the gold zone to confirm and develop reserves. The total budget for this underground development is $13 million.

Almost 5000 m of diamond drilling was done in 1985 on the property. This drilling was done to delineate the Marlhill gold zone located 800 m northeast of the North Zone. An additional 1200 m of drilling was done to explore an adjacent property optioned from the Schumacher Estate. Drill-indicated reserves on the Canamax Resources Bell Creek property are: 505 000 tonnes grading 6.7 grams gold per tonne for the North Zone ('A' horizon); 200 000 tonnes grading 7.1 grams gold per tonne for the Marlhill Zone and 272 000 tonnes grading 4.1 grams gold per tonne for the Bell Creek Zone. All zones are reported to contain potential for increasing reserves. While the North Zone ('A' horizon) is the target for the underground development, the Bell Creek Zone is situated closer to the shaft and will be readily accessible from underground for further exploration and development. As well, many drill intersections between the North Zone and the Bell Creek Zone can be evaluated from underground. The 'B' horizon of the North Zone will also be readily accessible for underground evaluation (Canamax Resources Incorporated, personal communication; various Northern Miner articles, 1985).

In late 1984, Canamax Resources Incorporated and joint venture partner Bruneau Mining Corporation discovered a new gold zone in the northeastern corner of German Township on property optioned from Clavos Porcupine Mines Limited. This 1984 discovery was made 305 m west of the original Clavos gold zone in Stock Township. By the end of December 1985, a total of 90 holes (over 22 000 m) will have been drilled on the property with 62 of these holes drilled in 1985. For the last six weeks of 1985, four drills were operating on the property. The total strike length of gold mineralization thus far outlined on this zone is 1500 m with the zone still open in both directions. Drilling thus far has concentrated on determining the horizontal limits of the mineralization. When this is done, fill-in drilling to establish continuity of the mineralization and to establish drill-indicated reserves will be done. The vertically dipping gold zone is located just south of the Pipestone Fault. All drilling is done from south to north and rocks intersected by the holes in this direction are; sediments, tuffs, mafic volcanic rocks, feldspar porphyry, sheared ultramafic rocks (talc chlorite schist fault zone), and massive ultramafic rocks. The gold occurs in quartz stockworks on the north and south contacts of the porphyry, which is between 2 and 30 m wide, auriferous, but not of economic grade (Canamax Resources Incorporated, personal communication; various Northern Miner articles, 1985).

DAVIDSON TISDALE MINES LIMITED/GETTY MINES LIMITED

Getty Mines Limited and Davidson Tisdale Mines Limited made an agreement in early 1984 to evaluate the latter company's gold deposit in Tisdale Township. Getty Mines Limited can earn a 50% interest in the property by spending $6 million. After over 40 000 feet (12 192 m) of diamond drilling in 1984, an indicated reserve of 823 850 tons (747 384 ton-

nes) grading 0.36 ounce gold per ton (12.3 g/t) with a potential for an additional 1.2 million tons (1.08 million tonnes) was published. Another deposit of 170 795 tons grading 0.33 ounce gold per ton (154 942 tonnes grading 11.3 g/t) was outlined.

Work done on the property in 1985 included the drilling of ten surface diamond-drill holes in January and February and four holes in May. A decision was made in the spring of 1985 to proceed with an underground program on the property to mine a 3000 ton (2721 tonne) bulk sample, accurately determine its grade, and to compare the results to an uncut drill-indicated grade. The resulting information would be used to calculate a more accurate cut grade in the previously outlined reserve blocks.

Dewatering of the underground workings began in June 1985. A headframe and hoist were erected over the old Horsehoe inclined shaft. A 70 m drift was driven from the shaft to connect to the old workings on the 500-foot (152 m) level near the centre of the mineralized zone.

Five horizontal diamond-drill holes and two inclined holes were drilled into the zone from the old drift. A 3000 tonne block of drift height was divided into areas of approximately 77 tonnes each. Each area was mined, stockpiled, crushed, and separately put through a sampling tower on surface.

Each sample was split three times in the sampling tower, resulting in the original 77 tonne sample being represented by a 5 gallon pail of sample for assay and a 45 gallon drum of sample for metallurgical testing. The backs of the underground excavation were chip sampled. Seventeen raises were driven up 55 m at +45° along the footwall of the ore to define and test vertical continuity. The total cost of this underground program was estimated to be $2 million.

Davidson Tisdale Mines Limited purchased 18 claims adjoining their property from Broulan Resources Incorporated. Drilling began in late 1985 to explore these claims. Davidson Tisdale Mines Limited is solely funding this drilling program without participation by Getty Mines Limited. It was reported that four holes intersected a previously known shallow north dipping quartz zone at a depth of 120 m. Visible gold was observed in these intersections (Getty Mines Limited, personal communication: personal observations; various Northern Miner articles, 1985).

ASARCO EXPLORATION COMPANY OF CANADA LIMITED

After test mining and milling 32 000 tons (29 029 tonnes) of material grading 0.225 ounce gold per ton (7.7 g/t) in 1984, Asarco Exploration Company of Canada Limited placed their underground Aquarius project on hold in 1985 except for 78 feet (24 m) of crosscutting on the 150 m level to a felsic body mineralized with gold. This body, 150 m south of the shaft, was previously discovered in 1984 by surface diamond drilling. Seven holes totaling 465 feet (142 m) of underground diamond-drill holes were drilled into this gold zone.

Asarco Exploration Company of Canada Limited was studying the feasibility of mining the whole gold-bearing carbonate horizon by open pitting instead of mining out the higher grade sections by underground methods. This approach requires much more definition drilling. One of the major obstacles to this plan is the presence of an esker system near the deposit which could act as an aquifer resulting in a water problem in the pit. Lack of financing and the present low price of gold is postponing any further developments on the property (Asarco Exploration Company of Canada Limited, personal communication, 1985).

WABIGOON RESOURCES LIMITED

In late 1985, Wabigoon Resources Limited began evaluating the old Hunter Mine property in Whitney Township. The company was recently reorganized, with financing amounting to $400 000 for 1985 and $350 000 for 1986 to carry out the project. By the end of 1985, six surface-drill holes totaling 3500 feet (1067 m) were drilled on the property. Underground workings, located partly on the property, were partially dewatered and the first two levels (232 feet (71 m) and 300 feet (91 m) below surface) were made accessible. Underground mapping and sampling were being carried out in December and 2000 feet (610 m) of underground diamond drilling was done. Testhole sampling of the walls was done with a jackleg percussion drill on the two levels. Geophysics and mapping were done on surface. Surface drilling off the ice on Porcupine Lake will be done during the winter of 1986 (Wabigoon Resources Limited, personal communication, 1985).

DIEPDAUME MINES LIMITED

Diepdaume Mines Limited is keeping the underground workings of the old Preston East Dome Mine pumped out to the 600-foot (183 m) level. In mid-November 1985, a program of grab sampling old chutes and muck left in some of the drifts from previous mining was done. A sampling program was conducted on the old tailings. Work in the mill was stopped for the winter. The mill is scheduled for completion in August 1986 (Diepdaume Mines Limited, personal communication, 1985).

PUISSANCE MINING CORPORATION

Puissance Mining Corporation took eight bulk samples totaling 178 tons (161 tonnes) from its property in Deloro Township for custom milling by Pamour Porcupine Mines Limited. Seven of these samples were taken from the carbonate zone along an evenly divided spacing for over 2000 feet (610 m). Two samples from adjacent sample locations assayed 0.15 ounce gold per ton (5.1 g/t) and 0.06 ounce gold per ton (2.1 g/t). The remainder assayed <0.03 ounce gold per ton (1.0 g/t). A bulk sample from the iron formation on the property in contact with the carbonate zone assayed 0.065 ounce gold per ton (2.2 g/t). The average grade of the eight samples was 0.055 ounce gold per ton (1.9 g/t). Plans for 1986 are to extensively sample between the two adjacent sections which had the highest grade. An exploration program to locate other carbonate zones on the property was recommended by the consultant (Dave Constable, Consultant, Sudbury, personal communication, 1985).

ST. ANDREW GOLDFIELDS LIMITED

St. Andrew Goldfields Limited, a subsidiary of Quebec Sturgeon River Mines Limited, continued the underground development program started in 1983 on its Stock Township gold deposit. Work included 792 feet (241 m) of lateral development on the second (325-foot, 99 m) level, 291 feet (89 m) on the third (450-foot, 137 m) level, and 967 feet (295 m) of lateral development on the fourth (575-foot, 175 m) level. A total of 1556 feet (474 m) of raising was done. Sublevel development totaling 1110 feet (338 m) was done between the first and second levels. Sublevel development totaling 1963 feet (598 m) was done between the third and fourth levels. In 1985, 45 000 feet (13 716 m) of underground drilling was done. The bottom of the shaft is at 884 feet (269 m) below surface in badly faulted and sheared ground. Plans in 1986 may be to deepen the shaft; however, drilling from the fourth level to below the bottom of the shaft will be done to see if the bad ground persists.

In order to hold the ground, the shaft extension must be changed from being rectangular to being a concrete, circular one. No underground development above the fifth level is planned for 1986. However, underground diamond drilling will continue.

Surface diamond drilling, totaling 7300 feet (2225 m), was done on an adjacent property optioned from Esso Minerals Canada and Labmin Resources Limited in lots 5 and 6, concessions I and II, Stock Township. The drilling is to continue into 1986. Encouraging results have been obtained with gold values intersected in rocks similar to those within the mine workings. This could represent a new zone or a faulted extension of the mine zone.

Published reserves are 735 625 tons (667 347 tonnes) at a gold grade of 0.135 ounce per ton (4.69 g/t). The current work is expected to increase this tonnage.

St. Andrew Goldfields Limited has a staff of 9 on the property and the contractors have 30 people (St. Andrew Goldfields Limited, personal communication, 1985; The Northern Miner, July 18, 1985).

ENERGY AND RESOURCES (CAM) LIMITED

Energy and Resources (CAM) Limited, in 1985, obtained an option to evaluate and test tailing deposits totaling 180 million tons (163 million) from nine mines in the Timmins area. These include the Dome; McIntyre; Delnite; Aunor; Buffalo Ankerite; Coniaurum; Paymaster; Preston East Dome; Vipond; Hallnor; and Broulan. Drilling was done in late 1984 and early 1985 on some of these sites. Average grade of these deposits is estimated to be 0.013 ounce gold per ton (0.49 g/t).

Energy and Resources (CAM) Limited is closely associated with Jimberlana Resources which is in the process of buying Noranda Incorporated's share of Pamour Porcupine Mines Limited. In late 1985, Energy and Resources (CAM) Limited reported that a feasibility study is nearing completion on a tailings reclamation project. Mining and milling rates studied are in excess of 250 000 tons (226 796 million tonnes) per month up to a maximum rate of 1.2 million tons (1.08 million tonnes) per month and a recovery of 50% to 60% (The Northern Miner, March 28, October 21, November 25, 1985).

KIDD CREEK MINES LIMITED

Kidd Creek Mines Limited, under their project development department, optioned the former Malga Porcupine gold property in Shaw Township from Gail Resources Limited. Kidd Creek Mines Limited was to spend $300 000 in evaluating the gold-bearing iron formation within six months to earn a 50% interest in the property. Twenty-two diamond-drill holes totaling 3991 feet (1216 m) were drilled to assess the iron formation for open pit mining potential. Poor results were obtained and the property was returned to Gail Resources Limited (The Northern Miner, May 30, 1985; Kidd Creek Mines Limited, personal communication, 1985).

EXPLORATION ACTIVITY

Exploration activity in the Timmins Resident Geologist area remained high in 1985. Almost all of the effort was placed on the exploration for gold in spite of the fact that its price has not improved over the previous year. Extremely weak base-metal prices discouraged everyone except Kidd Creek Mines Limited from conducting base-metal exploration programs. With present metal prices, it is easier to discover an economic gold deposit than an economic base-metal deposit. Most of the exploration expenditures, as in previous years, went into programs in the Abitibi "Greenstone" Belt. Active exploration continued in the "Swayze Belt" as reported by the Swayze Economic Geologist, this volume. Some of the projects carried out in 1985 in that part of the Abitibi Belt which lies within the Timmins Resident Geologist area are briefly described below:

KIDD CREEK MINES LIMITED

Kidd Creek Mines Limited focused their efforts on finding new base-metal deposits to add to reserves of the original Kidd Creek orebody and to keep the company's metallurgical complex in Timmins working at capacity over the long term.

The company also continued to explore for gold as part of an effort to diversify its mineral base. In 1985, base-metal exploration included drilling three diamond-drill holes (1070 m) in Godfrey Township; one hole (646 m) in Jamieson Township; two holes (657 m) in Jessop Township; eight holes (2123 m) in Prosser Township, and four holes (2210 m) in Kidd Township. One of the holes drilled in Kidd Township, was on ground optioned from Chance Mining and Exploration Company Limited to explore the possible faulted off extension of the small mineralized zone previously found.

Kidd Creek Mines Limited gold exploration program included: one diamond-drill hole (250 m) in Bristol Township; ten holes (3279 m) in Hoyle Township; four holes (941 m) in Lennox Township; eight holes (2455 m) in Lucas Township; ten holes (2401 m) in Matheson Township; seven holes (2002 m) in Ogden Township; and two holes (721 m) in Prosser Township.

As well, Kidd Creek Mines Limited carried out other activities in Clergue, Mahaffy, Tully, Carscallen, Reid, Macdiarmid, Wark, Robb, Cody, Whitney, and Tisdale Townships (Kidd Creek Mines Limited, personal communication, 1985).

NEWMONT MINES LIMITED

After spending $3 million in the last three years on gold exploration on optioned Tisdale-Whitney properties, Newmont Mines Limited abandoned the project. Nothing of economic significance was found and most of the options were dropped. Newmont Mines Limited is continuing a regional assessment and compilation of the Timmins area to develop exploration projects. The company examined many property submittals in 1985 (Newmont Mines Limited, personal communication, 1985).

KERR ADDISON MINES LIMITED

Kerr Addison Mines Limited cut 7 miles (11 km) of new grid and completed 14 miles (23 km) of geophysics in Tully Township. Four diamond-drill holes were drilled totaling 655 m. Three holes were drilled into E.M. anomalies and one hole into a high magnetic anomaly. Results were generally negative but one hole intersected anomalous gold values. No further work is planned in Tully Township. Kerr Addison Mines Limited also explored in Montcalm Township. Six line miles (10 km) of geophysics were done to define airborne conductors. Two diamond-drill holes totaling 420 m were drilled into conductors. Nothing of economic significance was intersected (Kerr Addison Mines Limited, personal communication, 1985).

UTAH MINES LIMITED

Utah Mines Limited completed a gold exploration program on claims optioned from R. Poirier in Bristol Township. Geological mapping, geophysical, and geochemical surveys were done. Two holes totaling 488 m were drilled under old trenching which had VLF and I.P. responses to the south. Results were disappointing. The highest core assay returned 270 ppb gold (Utah Mines Limited, personal communication, 1985).

FALCONBRIDGE LIMITED

Falconbridge Limited conducted a diamond drilling program east of the nine workings on their Hoyle Mine property on Whitney Township.

Falconbridge Limited optioned the southeast Deloro and Thorneloe Township properties of Comstate Resources and carried out stripping, sampling, and geological mapping (Falconbridge Limited, personal communication, 1985).

WESTMIN RESOURCES LIMITED

In Bond Township, Westmin Resources Limited extended a previously drilled hole from 229 m to 610 m. A quartz-feldspar porphyry with up to 2% pyrite was intersected (personal observation, 1985).

WESTFIELD MINERALS LIMITED

Westfield Minerals Limited prospected and conducted geological, geophysical, and geochemical surveys on 160 claims optioned from R. Allerston in Bristol Township. The option was subsequently dropped (Westfield Minerals Limited, personal communication, 1985).

ASARCO EXPLORATION COMPANY OF CANADA LIMITED

Asarco Exploration Company of Canada Limited conducted an overburden drill program on their claims in Robb Township early in 1985. A piece of float consisting of quartz carbonate veining and containing gold values was reported in an 1915 Ontario Bureau of Mines Annual Report (Volume 24, Part 3, p.60). The program was designed to test basal till up ice from this occurrence (Asarco Exploration Company of Canada Limited, personal communication, 1985).

B.P. RESOURCES CANADA LIMITED

B.P. Resources Canada Limited, Selco Division, carried out EM 37 and Pulse EM surveys on existing lines in Mann, McCart, Little, and Duff Townships. Some anomalies were located and may be drilled in 1986 (B.P. Resources Canada Limited, Selco Division, personal communication, 1985).

LAC MINERALS LIMITED

Lac Minerals Limited conducted a small geophysical program in Clergue and Sheraton Townships in 1985. The company also continued an exploration program started in 1984 in Fallon and Langmuir Townships doing geological mapping, geophysics, and basal till sampling with a plugger (Lac Minerals Limited, personal communication, 1985).

CLEYO RESOURCES INCORPORATED

Cleyo Resources Incorporated, in 1985, drilled two holes on a property in McArthur Township to investigate two conductors. Geological and geophysical surveys were done in Carscallen Township. An overburden drilling program with a plugger was done over electromagnetic anomalies in Matheson Township (Cleyo Resources Incorporated, personal communication, 1985; various Northern Miner articles, 1985).

COMSTATE RESOURCES LIMITED

Comstate Resources Limited completed a small overburden drilling program in the winter of 1985 on Night Hawk Lake in Cody Township (Comstate Resources Limited, personal communication, 1985).

DIEPDAUME MINES LIMITED

Diepdaume Mines Limited drilled a 305 m hole for geological purposes in the north part of Cody Townships late in 1985 (Diepdaume Mines Limited, personal communication, 1985).

DIPLOMAT RESOURCES INCORPORATED

Diplomat Resources Incorporated conducted a stripping, prospecting, and geological mapping program on the old Novell Porcupine or Excello property in Shaw and Deloro Townships. Old trenches and some old pits were cleaned out and resampled. Some additional trenching was done. A detailed geophysical program was completed. Gold values are found in iron formation and in quartz veining in a carbonate horizon located stratigraphically below the iron formation (K.A. Jensen, Consultant, Timmins, personal communication, 1985).

LOKI RESOURCES INCORPORATED

Loki Resources Incorporated conducted a stripping and sampling program on the western extension of the carbonate horizon which occurs on the Deloro Township property of Puissance Mining Corporation (personal observation, 1985).

MILNER CONSOLIDATED SILVER MINES LIMITED

Milner Consolidated Silver Mines Limited drilled one hole on their property 500 m north of the Davidson Tisdale deposit in Tisdale Township. No economic mineralization was intersected (Milner Consolidated Silver Mines Limited, personal communication, 1985; The Northern Miner, September 30, 1985).

UNITED KINGDOM ENERGY INCORPORATED

United Kingdom Energy Incorporated drilled 28 reverse circulation holes in Macklem Township during early 1985. The company drilled three diamond-drill holes (914 m total) to test the basal till geochemical gold anomalies and investigate a large carbonate alteration zone outlined by bedrock chips obtained from the overburden drilling. An intersection with visible gold, grading 13 g/t Au over 1.46 m, was obtained in one drillhole. A three-year option agreement has been made with Kidd Creek Mines Limited for the property. Kidd Creek Mines Limited is expected to begin exploring the property in mid 1986 (personal observation, drill core. 1985; Wm. MacRae, Consultant, Timmins, personal communication, 1985; The Northern Miner, October 21, 1985).

GOLDEIDT EXPLORATIONS INCORPORATED

Goldeidt Explorations Inc. drilled four diamond-drill holes in Macklem Township, to locate the source of basal till gold anomalies obtained in a reverse circulation drill program two years ago. Anomalous gold values were intersected (M. Pickens, Consultant, Midland Doherty, Toronto, personal communication, 1985).

Other companies and individuals conducting exploration programs in the Timmins area include: Aurelian Developers Limited (diamond drilling on claims optioned from Canreos Minerals (1980) Limited in Brackin Township); A. Amory (diamond drilled a 213 m hole in Price Township); D. Baker and J. Raine (stripping in Neill Township); P. Colbert (Denton, Carscallen Township); Magenta Development Corporation (Pharand Township); E.B. O'Neill (drilling in Whitney Township); J.P. Sheridan (geophysical surveys in Kidd Township); Walker Explorations (Sheraton Township); 655 Group Holdings Limited (Turnbull Township); E.G. Burns (Neill Township).

NORANDA EXPLORATION LIMITED

The biggest exploration effort for Noranda Exploration Limited in the Timmins area is the "Mountjoy Project" located on 224 patented and staked claims in Ogden and Deloro Townships. Noranda Exploration Limited is involved in a joint venture with Stan-west Mining Corporation by which the latter can earn up to 50% interest in the project by supplying $1 000 000 by the end of 1985 and a further $500 000 in 1986. The purpose of this program is to explore the extension of the Porcupine Gold Belt westward from the former Delnite Mine. Extensive diamond drilling, 40 holes totaling 40 000 feet (12 192 m), were drilled in 1985. Twenty of these holes were drilled on the former Desantis Mine property in Ogden Township optioned from L. Bonhomme. Ten holes were drilled in proximity to the mine workings. One hole was reported to have intersected 0.25 ounce gold per ton (8.6 g/t) over 21 feet (6.4 m), 1400 feet (427 m) below surface and below the bottom level of the mine which is 1125 feet (343 m) below surface. A wedged hole drilled off the above hole intersected 0.233 ounce gold per ton (7.9 g/t) across 27 feet (8.23 m) from a gold-bearing albitite dike. Four of the 40 (4125 feet, 1257 m), were drilled on property optioned from Comstate Resources Limited in Deloro Township just to the west of the Delnite Mine.

Other exploration projects completed by Noranda Exploration Limited in 1985 included: an airborne survey in Mann Township; three deep diamond-drill holes in a joint venture with Pamour Porcupine Mines Limited in Macklem Township, and three holes (1000 feet, 305 m) on a property optioned from J. Croxall in Bristol Township. It was announced in 1985 that Noranda Exploration Limited had dropped the option on the Holmer Property in Bristol Township after drilling three holes in 1984 (Noranda Exploration Limited, personal communication, 1985; The Northern Miner, 1985).

DOME EXPLORATION (CANADA) LIMITED

Dome Exploration (Canada) Limited had an active gold exploration program in the Timmins area in 1985. Seven holes totaling 10 000 feet (3048 m) were drilled in the northern part of Bond Township on overburden geochemical anomalies. Results were negative. Dome Exploration (Canada) Limited drilled 12 holes (8000 feet, 2438 m) in Bristol Township for geological purposes and to test electromagnetic anomalies over low magnetic areas. The program will continue in 1986.

The company also conducted an exploration program in Langmuir and Blackstock Townships on ground optioned from Melrose Resources Limited. The program consisted of two diamond-drill holes (1500 feet, 457 m), geophysics, and trenching. An I.P. survey will continue into 1986 (Dome Exploration (Canada) Limited, personal communication, 1985).

COMINCO LIMITED

Cominco Limited continued its aggressive gold exploration program in 1985. The company completed 60 line miles of magnetometer surveys in Tully Township; 14 overburden reverse circulation holes and 4 line miles of geophysics in Evelyn Township; 24 reverse circulation holes, 6 diamond-drill holes, and 8 line miles of geophysics in Matheson Township; 13 reverse circulation holes, 12 diamond-drill holes (6500 feet, 1981 m), and 2 line miles of geophysics in German Township; 7 reverse circulation holes, 1 diamond-drill hole (550 feet, 168 m), and 9 line miles of magnetometer surveys in Stock Township. Plans for 1986 include follow-up diamond drilling over basal till anomalies (Cominco Limited, personal communication, 1985).

LABRADOR MINING LIMITED

Labrador Mining Limited, formerly Hollinger Argus and Hollinger Exploration, closed their exploration division in 1985. Esso Minerals Limited is continuing to carry out some of their joint venture projects. Labrador Mining Limited, in a joint venture with Esso Minerals Limited but acting as operator, drilled five holes in Denton Township in 1985 intersecting pyrite, arsenopyrite with low gold values, and minor alteration (Labrador Mining Limited, personal communication, 1985).

ESSO MINERALS LIMITED

Esso Minerals Limited conducted an exploration program in Thorneloe Township in 1985, which included geological mapping, magnetometer surveys, I.P. surveys, and the drilling of three diamond-drill holes. Drilling will continue into 1986. One hole was reported to have intersected extensive carbonate alteration and anomalous gold values. One hole was drilled in Godfrey Township in late 1985.

Three holes were drilled in Tisdale Township intersecting calcitic alteration, and six reverse circulation holes were drilled in Bond Township. Esso Minerals Limited also conducted geophysical surveys and geological mapping in Godfrey, Turnbull, Carscallen, and Bristol Townships in 1985 (Esso Minerals Limited, personal communication, 1985).

CHEVRON CANADA RESOURCES LIMITED

Chevron Canada Resources Limited spent a large amount of time in 1985 investigating property submittals. Exploration programs included: 11 short diamond-drill holes in Dargavel Township; 20 km of geophysics and two diamond-drill holes in Turnbull Township; an airborne survey in Fournier Township; a small amount of geophysics in Robb Township, and geochemical and lithogeochemical surveys in Muskego Township. In addition, Chevron Canada Resources Limited conducted a stream geochemical program for gold in Whitney, Shaw, Tisdale, and Mountjoy Townships (Chevron Resources Canada Limited, personal communication, 1985).

QUEBEC STURGEON RIVER MINES LIMITED

Quebec Sturgeon River Mines Limited completed 14 600 feet (4450 m) of diamond drilling in 1985 in lots 1, 2, and 3 in concession I and II, Stock Township, lots 11 and 12, concession II, Taylor Township. It was reported that the geology is very complex. However, enough encouragement was received to continue drilling into 1986 (Quebec Sturgeon River Mines Limited, personal communication, 1985).

SWAYZE BELT ECONOMIC GEOLOGIST PROGRAM

INTRODUCTION

The Swayze Belt Economic Geologist Program was initiated in May of 1985. J.C. Ireland was hired as Economic Geologist. The program was designed to encourage exploration activities and to evaluate and document mineral occurrences. The Swayze Belt includes all or part of 49 townships totaling approximately 3500 km^2 (1375 square miles) located 80 km (50 miles) southwest of Timmins, Ontario.

Exploration activities proceeded at a moderate to high level through 1985 with gold as the major target. Over 80% of the area underlain by supracrustal rocks is currently staked and in good standing. Exploration activities have been noted on most of the patented ground in the Swayze Belt, which includes the more extensively developed and previously known gold, base-metal and industrial mineral occurrences in the area.

Twenty-four properties were visited during the 1985 field season. Several field trips were conducted to familiarize new companies and individual prospectors with the Swayze area.

HISTORY

The area has been explored periodically since the early 1900s. The extensive belts of iron formation received some attention around 1910, and during the years 1927 and 1928, some base-metal exploration was carried out in the southwest. Gold was discovered in 1931 by J.G. and J.L. Kenty on what is now the old Kenty Gold Mine property. Following this discovery, considerable prospecting took place in the southern part of the Swayze area, and a number of other discoveries of gold were made. Prospecting continued through the 1930s and again after World War II and into the early 1950s. Many of the known mineral occurrences were discovered during this time. The area received little further attention until the mid to late 1960s when a major upsurge of interest in base metals arose as a result of the Texas Gulf discovery in Timmins. Exploration activity remained moderate until 1980, when the price of gold rose to historic highs. Since that time, extensive exploration has taken place.

Several properties reached the underground development stage. Earliest reported production was from the Halcrow-Swayze Gold Mine which produced 40 ounces of gold from 211 tons of ore at an average grade of 0.19 ounce gold per ton in 1935.

The two largest past-producers in the Swayze area were the Jerome Gold Mine, located in south-

central Osway Township (from 1941 to 1943, production totaled 335 060 tons grading 0.17 ounce per ton gold which yielded 56 893 ounces of gold and 15 114 ounces of silver), and the Joburke Gold Mine, located in east-central Keith Township (from 1973 to 1975 and 1979 to 1981, production totaled 302 561 tons grading 0.09 ounce per ton gold which yielded 28 440 ounces of gold). Other documented past producers in the area include the Tionaga (Smith-Thorne) Gold Mine located in south Horwood Township (during 1938 and 1939, 6653 tons averaging 0.35 ounce per ton gold yielded 2299 ounces of gold), and the Kingbridge/Gomak Mine in Chester Township (during 1935 and 1936, 1387 tons at a grade of 0.07 ounce per ton gold yielded 98 ounces of gold). Canadian Crest Gold Mines produced a minor amount of gold in the early 1980s from a few open cuts in Chester Township. No base-metal production has been recorded historically, although M.W. Resources Limited (formerly Shunsby Mines Limited) has reported drill indicated reserves of 2.4 million tons of 2.7% zinc and 0.39% copper.

RECENT DEVELOPMENT

Orofino Resources Limited did little work on their gold deposit in Silk and Horwood Townships in 1985. A decline is planned to enter the former underground workings at depth, but no date has been given for commencement of the work. The company has published drill indicated reserve figures of 1.65 million tons grading 0.14 ounce gold per ton using a cut-off grade of 0.05 ounce gold per ton or 800 000 tons grading 0.21 ounce gold per ton at a cut-off grade of 0.11 ounce gold per ton (Orofino Resources Limited, personal communication, 1985; The Northern Miner, June 21, 1984).

Extender Minerals Limited is currently driving a decline on the former Cryderman or Ravena barite deposits located in southwest Penhorwood Township (Extender Minerals Limited, personal communication, 1985) (*see* "Industrial Minerals", this volume).

EXPLORATION ACTIVITIES IN THE SWAYZE BELT

Exploration activity in the Swayze Belt varied from moderate during the Spring and Fall to high levels during July, August, and December. The high levels of activity at the year end are due largely to the *availability* of flow-through money.

A brief description of most of the exploration activities carried out in the Swayze area during 1985 is described below.

Carl Creek Resources Limited carried out an extensive program of backhoe stripping and trenching, sampling, and geological mapping on the Kenogaming Township property optioned from Ingamar Explorations Limited. Most of the 1985 stripping was done on the old Johnsmith Mines property to examine induced polarization anomalies. Sampling of the exposed bedrock failed to return significant gold values. One trench, located on the east side of Akweskwa Lake and believed to be the eastward extension of the Dunvegan zone, returned a value of 0.157 ounce gold per ton from a 5 cm wide massive pyrite seam in sheared intermediate to felsic volcaniclastic rocks. Samples from the main Dunvegan zone returned values of up to 0.08 ounce gold per ton and 22% zinc. (M.P.H. Consulting Limited, personal communication, 1985; Resident Geologists Files, Ontario Ministry of Northern Development and Mines, Timmins).

Carison Mines Limited carried out a sampling program over areas stripped in 1983 in Rollo Township. The property includes the old Cyril-Knight and Aguara showings located south of Ridley Lake. The new sampling program was initiated to re-evaluate a 1983 channel sample that returned an average of 0.25 ounce gold per ton over 1.83 m (6.0 feet) from the Aguara showing (M.P.H. Consulting Limited, Toronto, personal communication, 1985).

Dome Exploration Limited carried out extensive ground geophysical and geological surveys over the central part of Newton Township during 1985. A 3050 m (10 000 feet) diamond drill program was completed in May of this year and Dome Exploration Limited reported a 6.3 m (20.7 foot) intersection averaging 0.18 ounce gold per ton in one hole which was drilled to test an Induced Polarization anomaly. The values occur in a carbonatized rhyolitic porphyry unit (dike or sill?) which intrudes carbonatized mafic metavolanics. A second 3050 m (10 000 foot) diamond-drill program started in November is testing this mineralized zone plus other new targets outlined during the past summer. Dome Exploration Limited holds the option on Newton, Dale, and Coppell Townships from Algoma Talisman Minerals Limited (Dome Exploration Limited, personal communication, 1985; The Northern Miner, May 9, October 7, 1985; personal observations, 1985).

Falconbridge Limited and joint venture partner Chevron Canada Resources Limited carried out a 1500 m (5000 foot) diamond-drill program on their Woman River iron formation property in Heenan and Marion Townships. Gold values were encountered in sulphide-filled cross fractures within the iron formation (Falconbridge Limited; Chevron Canada Resources Limited, personal communication, 1985).

Gogama Resources Limited completed a three hole, 285 m (932 foot) diamond-drill program on their property in Chester Township. Drilling was done to test Induced Polarization anomalies defined in 1984 (R.S. Middleton Exploration Services Incorporated, personal communication, 1985).

Hargor Resources Incorporated has completed ground surveys and a two hole, 250 m (800 foot) diamond-drill program on their Potier Township property. Brecciated magnetite iron formation was encountered in both holes (George Cross Newsletter, May 23, 1985; Resident Geologist's Files, Ontario Ministry of Northern Development and Mines, Timmins).

Inco Limited, through their exploration arm, Canico Limited, has reorganized its property situation in the Swayze Belt, giving up a large claim group in Swayze, Denyse, and Dore Townships. Canico Limited also dropped their option on the Burton Prospect in Esther Township after considerable work in 1984. New staking was reported by Canico Limited near the old Olive Gold Mine shaft located in northeast Cunningham Township. Immediately upon aquisition of an

option on the Quinterra Resources Limited Sylvanite Creek Property in Tooms Township, Canico Limited, as operator, and Golden Hope Resources Incorporated, a joint venture partner providing financing, began linecutting in preparation for ground survey. An overburden drill is on the property at the time of writing (December 10, 1985). Canico Limited will concentrate their exploration program on the northwest part of the grid which extends into Halcrow Township. This includes a part of the patented claims that make up the former Halcrow Swayze Gold Mine property in Halcrow Township. Regal Petroleum Limited holds the option on the other part of the patented claims group (Canico Limited, personal communication, 1985; Today's Market Line, November 27, 1985, Issue TML 229/85).

Murgold Resources Incorporated carried out a limited exploration program on their Chester Township property. The Gomak shaft has been dewatered and sampled. Vein material in the shaft pillar returned gold values over narrow widths (0.05 to 1.0 m) from surface and from the walls of the shaft. Limited stripping east of the shaft has exposed the vein along strike. Sampling of the Watts Vein was carried out and assays of up to 0.85 ounce gold per ton over two foot (0.6 m) widths were reported. A 175 foot (55 m) long decline is to begin on this vein pending financing. A new vein system was also discovered near the Watts vein (Murgold Resources Incorporated, personal communication, 1985).

Muscocho Explorations Limited drilled a 600 m (2000 foot) five-hole program in December 1985, on the property optioned from Jerome Gold Mines Limited (formerly Osway Explorations Limited) in Huffman and Osway Townships. All holes were drilled in Huffman Township on the north side of Oppeepeesway Lake. Most of the holes were to test mineralized showings on the old Jess-Mac property, but at least one hole tested electromagnetic anomalies farther west. There has been no recent report of work being carried out on the old Jerome Gold Mine located approximately 5 km (3 miles) west of the current drilling (Muscocho Explorations Limited, personal communication, 1985).

Noranda Incorporated (Exploration) was active on several properties in the Swayze area in 1985. On the International Rhodes Resources Limited joint venture property in Greenlaw Township, Noranda drilled eight holes to test gold and base-metal targets. A 215 m hole was drilled off Hotstone Lake to test the junction of two major fault systems, the north-south Hotstone Lake fault, and the east-west fault zone which runs along carbonatized komatiitic flows. The hole intersected a highly altered, silicified, brecciated, hematitic (intrusive?) rock mineralized with pyrite. A total of seven diamond-drill holes were drilled to test geophysical and geochemical base-metal targets on the Sultan Creek zone in east Greenlaw Township. The major target for this drill program was a surface base-metal showing discovered in 1984. Four holes were drilled to test the surface base-metal showing at depth and along strike. Base-metal mineralization was encountered in each of the four holes. Two soil geochemical targets were tested. One hole encountered sphalerite and minor galena mineralization and the other returned only low background values. One hole was collared to test a geophysical conductor. Heavily disseminated to massive pyrite and pyrrhotite was encountered in a lean cherty magnetite iron formation. No economic values were reported from this hole (Noranda Incorporated, personal communication, 1985; personal observations, 1985).

Diamond drilling on the Woman River occurrence in Mallard Township by the Noranda Exploration Limited/Berle Resources Limited Joint Venture intersected gold mineralization in a silicified, pyrite mineralized, porphyry unit within sheared mafic volcanic rocks. Over 1800 m (6000 feet) of drilling was scheduled to be drilled in 1985. Assay results to date from the first six holes include: BE-85-1, 0.147 ounce gold per ton over 3.68 m (12.1 feet); BE-85-3, 0.193 ounce gold per ton over 1.8 m (6.0 feet); BE-85-5, 0.102 ounce gold per ton over 2.8 m (9.1 feet); BE-85-6, 0.155 ounce gold per ton over 3.8 m (12.6 feet) (Noranda Incorporated, personal communication, 1985; The George Cross Newsletter, numerous articles, 1985).

Noranda carried out ground geological, geophysical, and geochemical surveys on their Genoa Township properties. Stripping was carried out on several targets but the results were inconclusive (Noranda Incorporated, personal communication, 1985).

Nu-Start Resources Corporation carried out a three hole, 400 m diamond-drill program east of Bagsverd Lake in Chester Township. No values of economic significance were encountered. The rocks drilled consisted of quartz-carbonate-sericite schist with pyritic zones (encountered in two holes), and chlorite-carbonate tuffs (The George Cross Newsletter, July 24, 1985, No. 142; Resident Geologist's Files, Ontario Ministry of Northern Development and Mines, Timmins).

Placer Development Limited completed a five hole, 600 m (2000 feet) diamond-drill program on their Dyment Lake property located in Denyes Township. Two holes, drilled to test induced polarization and electromagnetic targets, intersected pyritic and graphitic argillites within a series of dacitic tuffs. Three holes drilled under the surface exposure of an auriferous quartz vein intersected a dacitic feldspar porphyry, graphitic argillites, and rhyolitic tuffs. The porphyry is carbonatized and contains narrow quartz veins with altered (hematitic) margins containing pyrite. The best assay reported was from hole DEN-85-4 which returned a 0.27 m (0.88 foot) interval from 90.85 m to 91.14 m averaging 11.84 grams gold per tonne (0.345 ounce gold per ton). Placer has subsequently dropped the option on the part of the property drilled and has returned the claims to Messrs. J. Patrie and C.E. Bye (Placer Development Limited, personal communication, 1985; J. Patrie, personal communication, 1985; Resident Geologist's Files, Ontario Ministry of Northern Development and Mines, Timmins).

Quinterra Resources Incorporated is currently active on their Cree Lake property in Swayze Township with Golden Rim Resources Incorporated providing financing. Quinterra Resources Incorporated, as operator, has completed ground surveys and stripping and a diamond-drill program was under way at the time of writing (December 10, 1985).

Quinterra Resources Incorporated has signed a similar agreement with Western Pacific Energy Corporation, who will provide funding for exploration on Quinterra's Garnet Township properties. Quinterra is currently diamond drilling on this ground (Quinterra Resources Incorporated, personal communication, 1985).

Regal Petroleum Limited has completed a 1400 m (4600 foot), 14 hole diamond-drill program on the Halcrow-Swayze Gold Mine Zone (former Belcher Mining Corporation property) in west-central Halcrow Township. Drill targets are based on the results of an extensive trenching and sampling program carried out earlier this year. In the area of trenching, gold is believed to be associated with closely spaced fracture zones filled with pyrite in felsic to siliceous tuffs and pyroclastic units containing small (5 to 15 mm) rhyolitic fragments. The entire felsic package is approximately 60 m thick, but mineralization is confined to narrow shears 0.1 to 2 m wide. The entire sequence is carbonatized and sericitized to varying degrees. A few silicified zones and some quartz veining have been observed elsewhere on the property (David R. Bell Geological Services Incorporated, for Regal Petroleum Limited, personal communication, 1985; personal observations, 1985).

The Sangold Project in Keith Township has completed an extensive stripping and sampling program over a part of the old Hoodoo Lake Gold Mines property. Gold values have been obtained within crosscutting quartz-carbonate veins mineralized with sulphides. These veins occur within two zones of highly foliated and extensively sheared, carbonatized pillowed mafic flows and associated mafic tuffs. Several ages of mafic dikes and sheared porphyry dikes and sills intrude the mafic sequence, cutting the stratigraphy at low angles. A late lamprophyre dike cuts all other rock types observed. The property owner is currently negotiating with a resource company on an option agreement (G. Sanford; M.P.H. Consulting Limited, Toronto; various mining exploration companies, personal observations, 1985).

Storiman Exploration Limited completed a 900 m (3000 foot) drill program on 33 claims optioned from Noranda Exploration Limited in 1984. Drilling was concentrated on the further evaluation of a sheared diorite containing auriferous quartz veins. Two holes intersected "ore grade" mineralization at depths of <90 m (The Northern Miner, January 31, 1985).

Sulpetro Minerals Limited carried out a small diamond-drill program on the old Rundle Gold property located in southeast Newton Township, to test areas away from the known deposit, which has an estimated reserve of 100 000 tons averaging 0.29 ounce gold per ton. Sulpetro Minerals Limited, which was recently sold to Americ Mines Limited, shares ownership of the property 50/50 with Labrador Mining Limited (Hollinger-Argus) who is currently in the process of selling their interest (Sulpetro Minerals Limited, personal communication, 1985).

Swayze Resources Limited carried out a trenching and sampling program on their Swayze Township property. Grab samples and channel samples over narrow widths from the Hopkins number 1 vein contained gold values. Samples were collected from a narrow quartz-carbonate vein system in carbonatized and silicified pillowed mafic volcanic rocks. The best channel sample reported was 0.291 ounce gold per ton over 1.2 feet. One plugger dust sample reportedly assayed 0.61 ounce gold per ton (K.A. Jensen Exploration and Consulting Services, Timmins, personal communication; personal observations, 1985).

Ultrex Petroleum Limited completed a 600 m (2000 foot) diamond-drill program on their Horwood Township property optioned from E.J. Korba of Connaught, Ontario. The property lies east and south of the Charlebois patents, located on the east shore of Horwood Lake. Drilling was done to test induced polarization and electromagnetic targets outlined earlier in the year (North American Mining Exploration Corporation for Ultrex Petroleum Limited, personal communication, 1985).

Utah Mines Limited (Exploration) has completed ground surveys on their property in Keith and Muskego Townships. Follow-up stripping on coincident Induced Polarization/soil geochemical anomalies has exposed a sequence of foliated and carbonatized mafic to intermediate volcanic flows and related volcaniclastic rocks carrying anomalous gold values associated with sulphide mineralization. Utah plans a drill program early in 1986 (Utah Mines Limited (Exploration), personal communication, 1985; personal observations, 1985).

Weaco Resources Limited completed an airborne geophysical survey over its large claim group in Benton and Mallard Townships. Ground surveys were initiated this fall (Weaco Resources Limited, personal communication, 1985).

Other companies and individuals not previously mentioned but actively exploring in the Swayze Belt include: Mr. A. Maskovich (geobotanical survey over three claims in Keith Township); Blue Falcon Mines (geology and geophysical surveys on their properties in Huffman and Osway Townships); Chevron Canada Resources Limited (staking and ground surveys on their Muskego/Foleyet Townships property); Comstate Resources Limited (stripping and geochemical work on their Reeves-Sewell Townships Antimony-Arsenopyrite-gold occurrence); Emerald Isle Resources Incorporated (ground surveys on their Chester-Yeo Townships properties; planning a work program on the former Kenty Mine property in Swayze Township, formerly held by Heron Limited Resources); Folkstone Resources Limited (ground surveys on their property located in Cunningham, Greenlaw, Denyes, and Swayze Townships); Greyhawk Resources Limited (ground surveys on their property in northeast Greenlaw Township); Mr. J. Landers property (stripping and sampling on his Horwood Township claims); Kidd Resources Limited (stripping, sampling on their Chester and Yeo Townships property); Manville Canada Incorporated (ground surveys on properties in Denyes and Penhorwood Townships); Neville Explorations (airborne geophysical survey in Mallard Township); Mr. R. Tremblay property (stripping and trenching on his Sewell Township property); Mr. W. Karvinen (ground surveys on his Penhorwood Township property); and Kidd Creek Exploration Limited (diamond drilled one hole to a depth of 121.9 m (400 feet) in Cunningham Township).

ONTARIO GEOLOGICAL SURVEY ACTIVITIES

In 1985 as in 1984, there were no Precambrian Geology Section programs in the Timmins Resident Geologist area. Ontario Geological Survey activities were limited to work done by the Geophysics/Geochemistry Section on the Night Hawk Geophysical Test Range and to various interdisciplinary studies done on the four townships in this area which fall under the Black River-Matheson Program (BRIM).

GEOPHYSICS/GEOCHEMISTRY SECTION

During 1985, staff of this section continued studies on the Night Hawk Geophysical Test Range. These studies included surveys employing the ELFAST RTX/HL-30 and the recently upgraded MAXMIN III+ frequency domain electromagnetic systems.

This section also completed a correlation of airborne and ground electromagnetics with sonic drilling results in the Black River-Matheson area.

BLACK RIVER–MATHESON (BRIM) PROGRAM

Engineering and Terrain Geology Section

In 1984, as part of the BRIM program, sonic drilling was undertaken in a four by four township block at the western end of the program area. In 1985, fill in drilling was completed in this area which includes Clergue, Stock, Bond, and Sheraton Townships. Results from this drilling will be released in mid-1986.

Mineral Deposits Section

J. Malczak, Geologist, Mineral Deposits Section, continued investigation of the St. Andrew Goldfields deposit in Stock Township. The work in 1985 continued the study initiated in the previous field season. Selected levels of the underground development were examined and sampled to provide more complete information on specific cross-sections.

ONTARIO GEOSCIENCE RESEARCH GRANT PROGRAM

During 1984 and 1985, grant recipients with projects directly related to the Timmins Resident Geologist area are listed below:

Grant 138

Mineralogy and Geochemistry of the Chrysotile Asbestos Deposits of Ontario: A Progress Report on the Stable Isotope and Boron Survey; J. Ozoray, F.J. Wicks, and M.D. Higgins.

Grant 192

Geochemical Exploration for Gold; Ian Nichol, and Gene S. Shelp.

Grant 202

Sulphur Isotope Studies of Archean Gold Deposits; H.P. Schwarcz, and C.E. Rees.

Grant 233

The Dating of Ontario's Gold Deposits; A. Masliwec, Derek York, P. Kubida, and C.M. Hall.

Grant 236

Geological, Fluid Inclusion, and Isotopic (Carbon and Sulphur) Studies of Au-Quartz Carbonate-Pyrite-Scheelite Vein Mineralization and Intrusion-Hosted Cu-(Au-Mo) Mineralization in the Hollinger-McIntyre System, Timmins, Ontario; E.T.C. Spooner, P.C. Wood, D.R. Burrows, A.V. Thomas, and S.R. Noble.

ONTARIO MINERAL EXPLORATION PROGRAM (OMEP)

In 1985, a total of 77 programs were designated for OMEP assistance in the Porcupine Mining Division. Seventy of these programs were in the Timmins Resident Geologist area. Total budgeting expenditures amounted to $29 703 236. Of this total, $21 130 630 are expenditures eligible for OMEP. OMEP tax/grant credit assistance for the Porcupine Mining Division have increased by almost 90% over tax/grant credits for 1984.

7. Kirkland Lake Resident Geologist Area, Northern Region

Howard Lovell[1], Gary Grabowski[2], David Guindon[3], and Alexander Bath[4]

[1]Resident Geologist, Ontario Ministry of Northern Development and Mines, Kirkland Lake

[2]Resource Geologist, Ontario Ministry of Northern Development and Mines, Kirkland Lake

[3]Core Library Geologist, Ontario Ministry of Northern Development and Mines, Kirkland Lake

[4]Economic Geologist, Ontario Ministry of Northern Development and Mines, Kirkland Lake

INTRODUCTION

The Kirkland Lake Resident geologist area coincides with the Larder Lake Mining Division. Assessment work credit assigned in 1985 totaled 460 183, the second most in the history of the Larder Lake Mining Division (*see* Table 7.1). Active claims numbered 23 974, the most ever. According to "The Explore Report . . . " (Gartley 1985), the 1984 expenditures, for the townships that comprise the Kirkland Lake Resident Geologist area. the most recent available, for "outside and general exploration" were $9 890 662, about 17% of the Ontario total. However, this estimate may be low, because the Ontario Mineral Exploration Program (for exploration by only those organizations that do not produce minerals in Ontario) projected expenditures of $13 170 176 for 1985. "Mine and on-property exploration" totaled $1 296 890, about 14% of the Ontario total, and "mine and on-property development" expenditures were $20 393 033, about 10% of the Ontario total. The total value of production (including iron pellets, gold, silver, barite, and serpentine filler) for 1983, the most recent figure available, was $116 247 183 (Weatherson 1985). Thus, mineral resources revenue in the Kirkland Lake Resident Geologist area for a single 12-month period is estimated to total about $150 million.

An interpretation of the Mining Act in 1978, regarding the Bear Island Indian Caution laid in 1973, has for the past eight years prevented the recording of mining claims and consequently prevented most exploration and any possible ensuing production in one-quarter of the Larder Lake Mining Division.

RESIDENT GEOLOGIST STAFF ACTIVITIES

Permanent staff includes: Howard Lovell, Gary Grabowski, and Faye M. Boucher, Secretary. Geological Assistant Todd Beckett worked a nine-month contract. Assistance was provided during various periods by Gordon Fitzgerald, Alex Jovan, and Bill Dennis through the Special Employment Program. Clerical assistance was provided for various periods by Pamela Savarie (Black River-Matheson project) and Gina Viskovich (Experience '85).

The Black River-Matheson project employed Alex Bath as Economic Geologist, Nicholas Cox (5 months) as Geological Assistant, and Data Folio Geologist Kamal Kalicharran. Two groups of ten Junior Rangers, for one week each, stripped soil to improve bedrock exposures for field trips in the Matheson and Larder Lake areas.

Activities of the Resident Geologist Office included:

1. responding to 2400 inquiries from exploration, mining and government personnel, and the general public.
2. preparing 44 reports on mineral property examinations, diamond drill logs, field trips, and technical papers.
3. guiding 11 geological field trips to Kirkland Lake-Larder Lake area gold occurrences by groups of mineral explorationists, government, university, and foreign geologists, and two Ontario Ministry of Natural Resources Junior Ranger camps.
4. responding to Road Proposals and Forest Management Agreements, Mining Rights Withdrawals, Mining Hazard Lands reviews, etc.
5. indexing and filing for ready retrieval the assessment work representing 460 183 "man days".
6. indexing and filing 200 additional articles in the technical library, which now fills six filing cabinets.
7. attending Canadian Institute of Mining and Metallurgy symposia, local executive, local and District Three Council and (or) local meetings at Kirkland Lake, Cobalt, Timmins, and Ottawa.

MINING ACTIVITY

During 1985, ten mines operated in the Kirkland Lake Resident Geologist area, five producing gold and by-product silver, two producing and one developing silver and by-product cobalt, one producing iron ore pellets, one producing barite, and one producing serpentine filler. In addition, a shaft is being sunk at one developing gold mine. Total gold production in the Larder Lake Mining Division by the end of 1984 is shown in Table 7.3.

Lake Shore Mines Limited continued mining its crown pillar for gold-silver ore via a scoop tram decline ramp, and renovated No. 5 shaft to the 1400-foot level, with the possiblity of eventually mining down to the 3950-foot level. Proven underground reserves (Canadian Mines Handbook, 1985-86) are 312 000 tons averaging 0.35 ounce gold per ton.

At the Macassa gold-silver mine of Lac Minerals Limited, the planned deepest single-lift vertical shaft in the western hemisphere (ultimate depth 7275 feet or 2205 m), reached more than 6600 feet (2000 m) deep.

The McBean gold-silver mine, owned by Inco Limited and Queenston Gold Mines Limited and operated by Inco Limited, continued open pit production and milling of gold-silver ore.

Argentex Resource Exploration Corporation intersected 30 m of anomalous gold deep hole drilling,

down dip from the Canamax Resources Incorporated "Mattawasaga" zone on the Argentex 50-claim property in Holloway Township.

Barrick Resources Corporation diamond drilled several thousand metres delineating the McDermott gold discoveries in Holloway Township and exploring nearby claims in Harker Township, and began sinking a 1400-foot (425 m) shaft to access the main ore zone. Reported reserves are more than 1.3 million tons averaging 0.18 ounce gold per ton (The Northern Miner, November 25, 1985).

Canamax Resources Incorporated and affiliated Bruneau Mining Corporation diamond drilled several thousand metres. Several of the holes were drilled at the Canamax gold discoveries in Holloway Township.

Falconbridge Limited diamond drilled the Mitchell-Hearst claims of Many Metals Mines Limited for gold.

Goldbrook Explorations Incorporated de-watered the upper two levels of the Gold Hill Mine in Catharine Township.

Golden Shield Resources Limited diamond drilled 1600 m and began de-watering the shaft at the Catharine Township gold past producer of Mirado Nickel Mines Limited.

Lenora Explorations Limited diamond drilled in the known gold-bearing stratigraphic zone on Golden Harker claims.

Maude Lake Gold Mines Limited diamond drilled additional holes at its Beatty Township "Argyll" gold deposit and blasted and sampled (by means of a sampling tower) the main gold zone that reaches surface.

McGarry Resources Incorporated diamond drilled its McGarry Township gold prospect.

Newmont Exploration of Canada Limited diamond drilled in Bradette, Hoblitzell, and Noseworthy Townships on the Ontario extension of Quebec's Casa-Berardi gold-bearing stratigraphic zone. Hole 85-A-8 intersected a cherty volcanic formation and returned values of 0.116 ounce gold per ton over 25 feet including an 8-foot section grading 0.27 ounce gold per ton (The Northern Miner, June 20, 1985).

Shenandoah Resources Limited diamond drilled and trenched several properties in Boston, McElroy, Pacaud, and Catharine Townships.

DRILL CORE LIBRARY

The Drill Core Storage Library (Lithotheque) for the Larder Lake Mining division was opened in June of 1984. At present, 122 866.4 m of core are stored, representing 167 551.9 m of drilling.

In 1985, approximately 30 150 m of drill core were collected, catalogued, and stored. Figure 7.2 shows the location of the drillholes from which the core has been stored in the library. Table 7.5 lists a summary of core stored for each township. As of December 1, 1985, users and inquiries numbered 367.

The capacity of the library is approaching the limit; to delay reaching capacity, some core, particularly from areas of high density drilling, will be moved to an exterior box-on-box site, to be stored on pallets. In general, one out of every three or four holes will remain in the library, with the remainder stored outside the library.

The Drill Core Library issues quarterly catalogues listing all drill core collected. Supplements listing new additions are sent out at the end of each intervening month.

Assistance at the Core Library was provide by: F. Kiernicki, Geological Assistant; A. Charbonneau, D. Bruce, G. Fitzgerald, M. Shortt, and G. Pelletier, Mining Sector Works Program; and M. Gelinas, Ontario Youth Corps Program.

The Core Library is located 5 km west of Kirkland Lake on the southern side of Highway 66, at the Ontario Ministry of Natural Resources District Office. Persons wishing to examine or donate core, or wishing to receive catalogues and updates should telephone (705) 642-3222 Ext. 169, or write to:

OPERATION BLACK RIVER–MATHESON (BRIM)

INTRODUCTION

Operation Black River-Matheson (BRIM) is a multidiciplinary geoscience program focused on a 40-

township block extending from Night Hawk Lake eastward to the Ontario-Quebec interprovincial boundary (Figure 7.3). The program has been designed to stimulate the economy of Northern Ontario in the long term via mineral exploration incentives provided through development of an exploration database. This database will ideally contribute to the discovery of mines in the area. The goals of the five-year program (now in its third year) are being realized through contributions from the Engineering and Terrain Geology, Geophysics/Geochemistry, Precambrian, and Mineral Deposits Sections of the Ontario Geological Survey and the Kirkland Lake and Timmins Resident Geologist offices.

GENERAL GEOLOGY

The BRIM area is located in the Superior Structural Province of the Canadian Shield and is underlain by Early Precambrian (Archean) metamorphosed supracrustal and plutonic rocks of the Abitibi "Greenstone" Belt. Middle Precambrian (Huronian) sedimentary rocks unconformably overlie the Early Precambrian rocks in one part of the area. Overburden, consisting mainly of Pleistocene tills, esker deltaic sands, and lacustrine varved clays is present over the great majority of bedrock surface. Local bedrock geology is dominated by sub-greenschist to greenschist facies, volcanic and sedimentary rocks which have been intruded by ultramafic to felsic sills, stocks, and batholiths, and volumetrically minor diabase dikes. Two major east-west trending regional faults traverse the area: the Pipestone Fault (and its extension to the east) and the Porcupine-Destor "Break". The Porcupine Destor "Break" is a structurally complex fault zone which constitutes a major structural and lithologic discontinuity along much of its extent within the BRIM area.

Recent mapping in this part of the Abitibi Belt (Jensen and Langford 1985) indicated that the volcanic stratigraphy may be subdivided into a series of major cycles, each of which is characterized by lower, middle, and upper parts of, respectively, dominantly komatiitic, dominantly tholeiitic, and dominantly calc-alkalic affinity. Regionally, lithologies present in the BRIM area correspond to the upper part of volcanic cycle II (calc-alkalic Hunter Mine Group) and to the lower (komatiitic Stoughton-Roquemaure Group), middle (tholeiitic Kinojevis Group), and upper (calc-alkalic Blake River Group and alkalic Destor-Porcupine Complex) parts of volcanic cycle III (MERQ-OGS 1983).

ONGOING ACTIVITIES

The surficial geology of BRIM area has been mapped at a scale of 1:50 000 by Quaternary geologists of the Engineering and Terrain Geology Section of the Ontario Geological Survey. The release of 1:50 000 scale Quaternary Geology maps of the Matheson (Vagners 1984) and of the Porquis Junction, Watabeag River, and Lightning River areas (Richard and McClenaghan 1985a, 1985b; Vagners and Courtney 1985; Richard 1984) complements previous mapping at the same scale in the Magusi River (Baker *et al.* 1982) and Ramore (Baker *et al.* 1980) areas.

Data pertaining to gold grain distribution (Baker, Steele, McClenaghan, and Fortescue 1984) and preliminary results of bedrock analysis (Jensen *et al.* 1985) from the 1984 Ontario Geological Survey sonic overburden drilling program have been released. Commencing in January 1986, data sheets containing additional information relating to sonic drill cores recovered during 1984 are anticipated to be released. The data sheets will include such information as graphic logs with accompanying interpretation; the number, size, and shape of gold grains recovered; geochemistry of minus 250 and minus 10 mesh fractions; and mineralogy and geochemistry of heavy minerals. Results of the 1984 backhoe sampling program (Baker, Steele, and Fortescue 1984) are also expected to be released in data sheet format during Spring 1986.

Ontario Geological Survey Open File Reports pertaining to sonic drilling methodology and heavy mineral processing (cf. Baker, Steele, and McClenaghan 1985) as well as to the mineralogy and geochemistry of the 1984 sonic drilling bedrock samples are anticipated to be released in January and March/April 1986, respectively.

Ontario Geological Survey Quaternary Geologists continued the overburden drilling and backhoe-assisted trenching program begun during 1984 (Baker, Steele, and McClenaghan 1985). Preliminary interpretation of bedrock samples recovered during the course of this drilling as well as the distribution of gold grains within the overburden sections of the core are expected to be released in March 1986 (cf. Baker, McClenaghan, and Steele 1985).

Geophysicists of the Geophysics/Geochemistry Section of the Ontario Geological Survey completed a regional gravity survey in Northern Ontario which included the southern half of the BRIM area (Gupta *et al.* 1984; cf. Gupta 1984). Results of the survey are expected to be released in the near future. An evaluation of the effectiveness of using electromagnetic measurements to estimate the thickness of Quaternary overburden in the BRIM area appeared late in 1985 (Pitcher 1985).

Geologists with the Precambrian Section of the Ontario Geological Survey continued to map the bedrock geology in part of the BRIM area during 1985 (Johnstone and Trowell 1985a). During 1985, the eastern half of McCool and the northern parts of Hislop, Guibord, and Michaud Townships were mapped. Preliminary results of this mapping were released late in 1985 (Johnstone and Trowell 1985b). Bedrock geology maps of the Ramore area (Jensen 1985a, 1985b, 1985c) were also published.

Geologists with the Mineral Deposits Section of the Ontario Geological Survey continued to study selected deposits located within the BRIM area. Activities during 1985 were focused on gold mineralization in the Holloway-Harker-Thackeray Township area (Whittaker 1985), on gold-silver-copper mineralization and associated alteration at the Ross Mine in Hislop Township (Troop 1985a, 1985b), and at the St. Andrew Goldfields (Stock Township) and Maude Lake (Beatty Township) gold deposits (Malczak 1985a, 1985c, 1985d). An Ontario Geological Survey Open File Report concerning the potential of the BRIM area to host industrial minerals is expected to be released during 1986 (cf. Malczak 1985b).

An inventory of the peat and peatland resources of the Timmins-Kirkland Lake area was released during 1985 (Northland Associates Limited 1985).

Compilation of Geological Data Inventory Folios (GDIFs) by K.D. Kalicharran and staff at the office of the Resident Geologist in Kirkland Lake is ongoing. During 1985, GDIFs for the townships of Bowman, Carr, Currie, Frecheville, Lamplugh, Marriott, Stoughton, and Taylor (GDIF Numbers 271, 265, 270, 268, 267, 273, 269, and 264, respectively) were released. Compilation for an additional 14 townships has been completed (Figure 7.4) and these are expected to be released in the near future. GDIF compilation for each township within the BRIM area is expected to be completed during 1987.

As of November 30, 1985, about 34 000 m of diamond drill core from 350 holes representing in excess of 51 000 m of diamond drilling in the BRIM area have been catalogued and shelved and are available for examination and sampling at the Larder Lake and Porcupine Mining Division Drill Core Storage Libraries (*see* Figure 7.2). Also available for examination are bedrock samples from the 1984 Ontario Geological Survey sonic overburden drilling program. Cataloguing of about 12 000 hand sample rock specimens is ongoing by the staff at the Larder Lake Mining Division Core Library collected from the eastern and south-central parts of the BRIM area by L. Jensen during the course of his bedrock geological mapping. When fully catalogued, details such as township location, NTS and UTM coordinates, rock type, lithology, geochemical and assay data (where applicable), and storage location for each sample will be stored in a computerized database to optimize accessibility and facilitate use of this data.

As part of Operation Black River-Matheson, an Economic Geologist is based in Kirkland Lake to encourage exploration activity at the local level by being available to all members of the exploration community as a source of exploration-related information and advice. Efforts of the Economic Geologist are directed toward the mining, exploration, and prospecting communities to promote activity in the BRIM area, to catalyze the property optioning process, to interface between the public and private sectors, and in general to provide services which facilitate exploration. Specifically, the economic geologist is available to: 1) assist local prospectors with property visits, advice, and assessment file searches; 2) document new mineral occurrences in the BRIM area; 3) more fully describe previously documented mineral occurrences; 4) compile data relevant to exploration; and 5) help "orient" new workers or potential new workers to the area. A long term goal of the program is the compilation of a locally accessible geoscience database for the BRIM area.

Activities of the Black River-Matheson area Economic Geologist during 1985 are described in Bath (1985a). In brief:

1. Most of the field season during 1985 was spent examining mineral showings in the field. Individual deposits examined during 1985 are shown on Figure 7.5 and are briefly described in Table 7.6.
2. A bedrock geological compilation map (scale 1:100 000) of the BRIM area has been generated from 57 provincial maps and reports which were

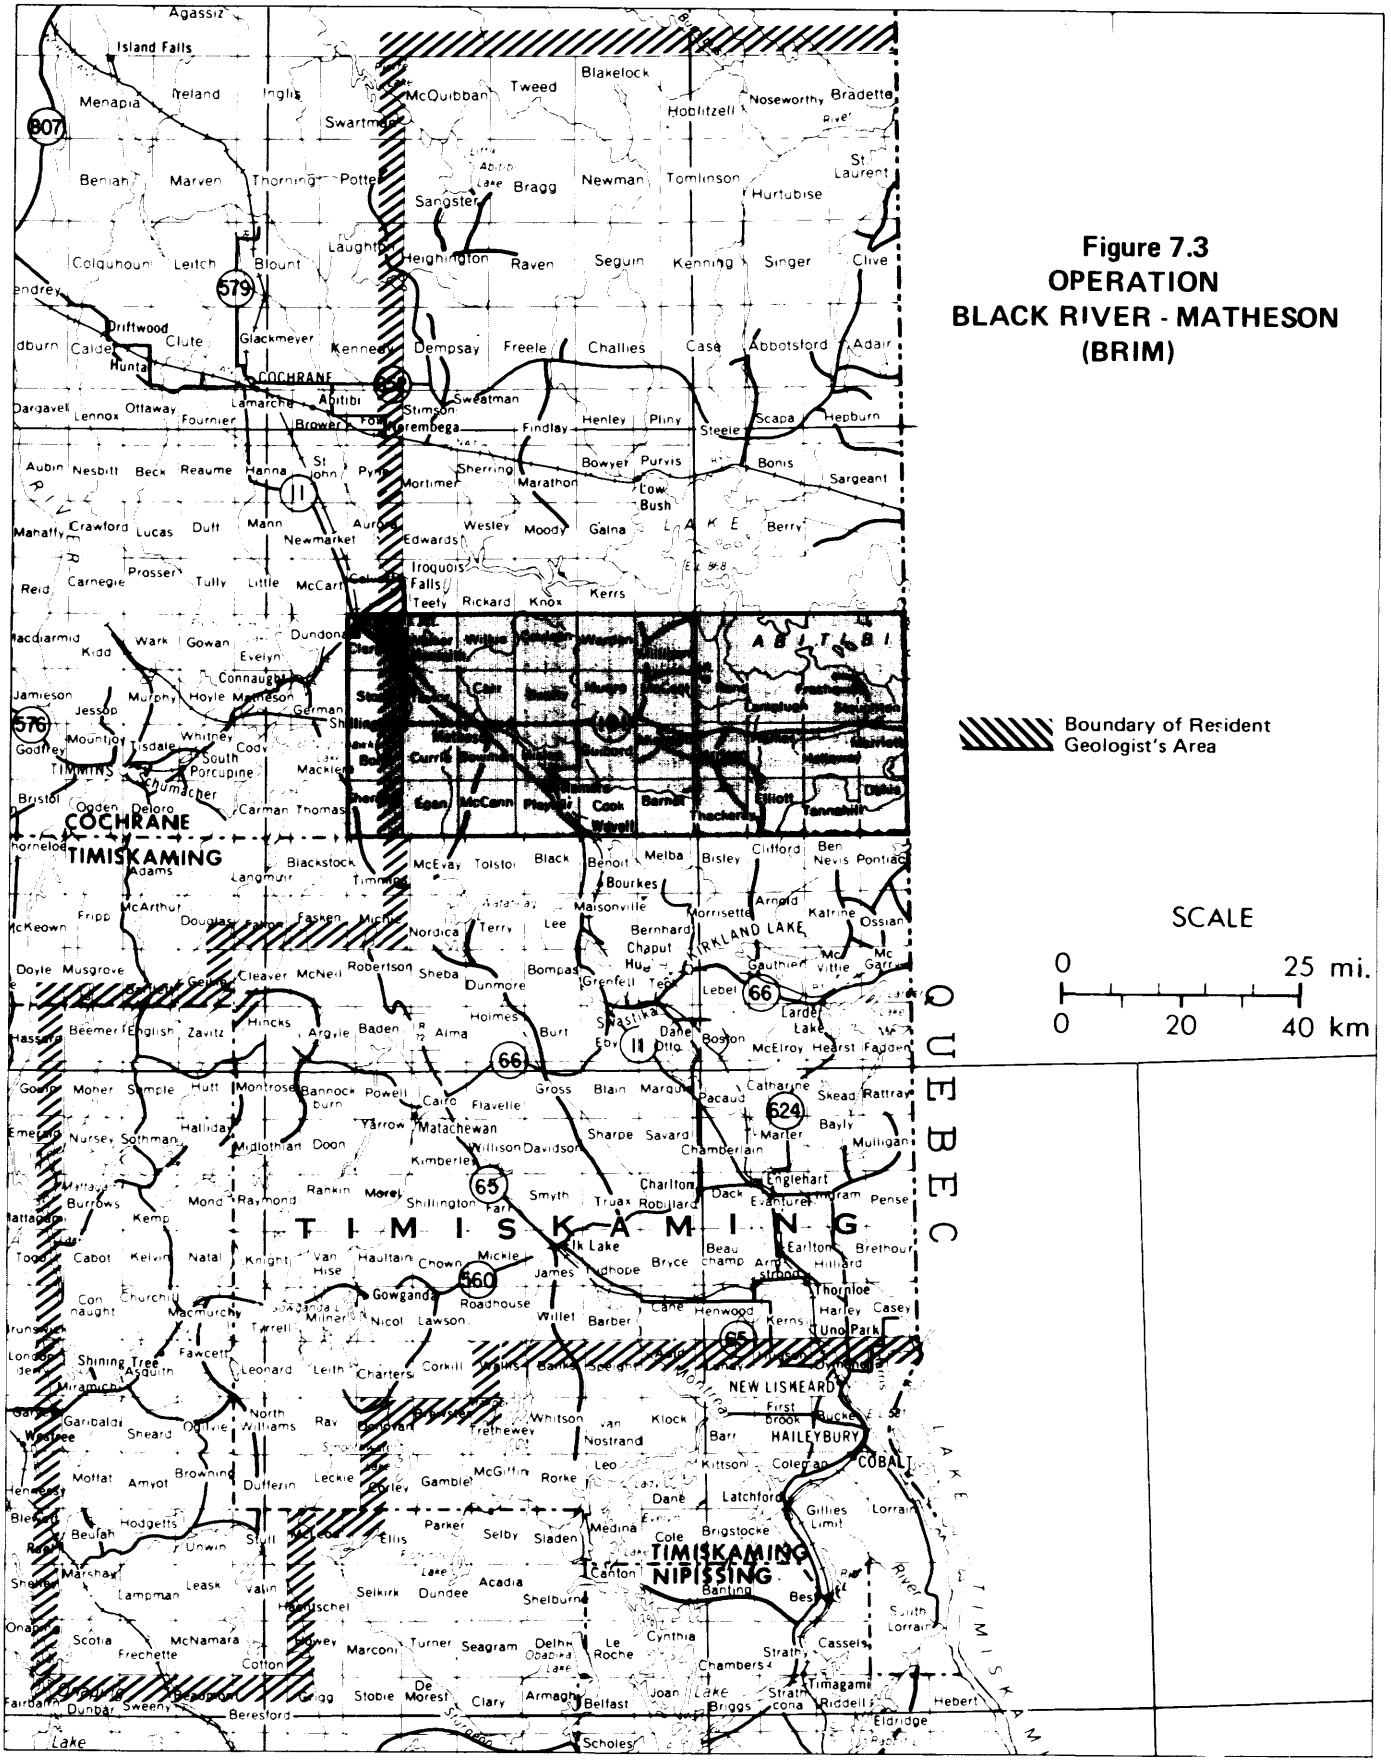

Figure 7.3
OPERATION
BLACK RIVER - MATHESON
(BRIM)

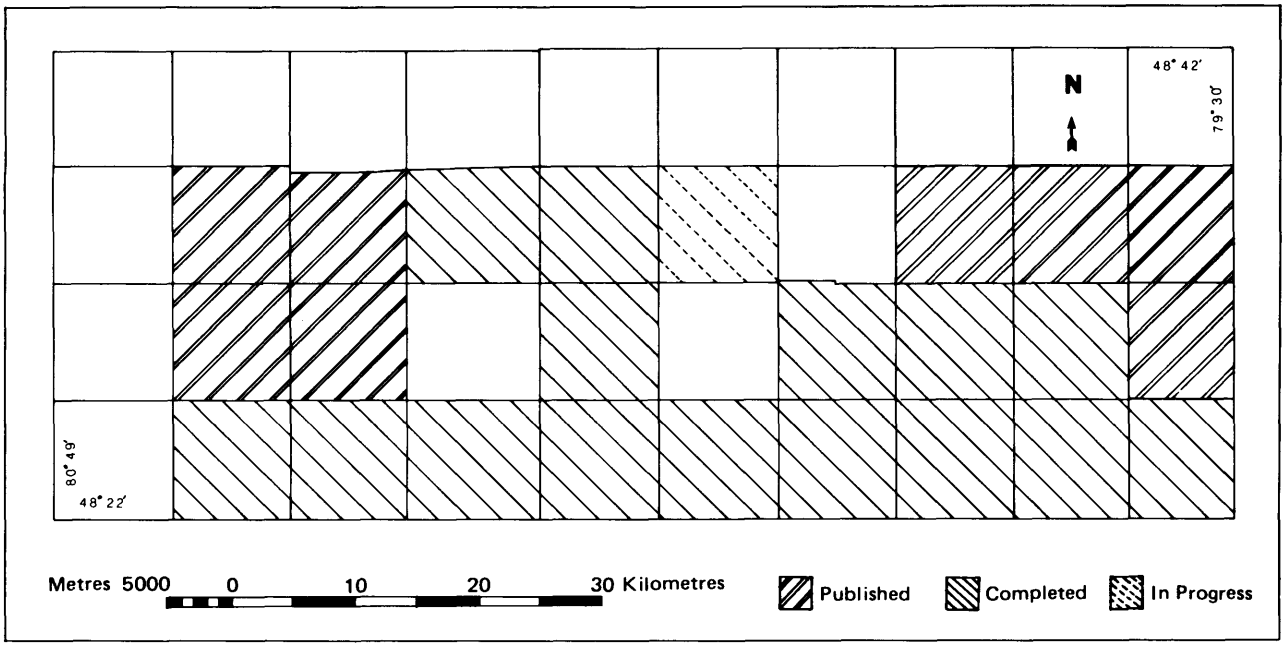

Figure 7.4 . BRIM Area GDIF Status

available during the first half of 1985. This map will be updated early in 1986 to incorporate the results of recent mapping by the Ontario Geological Survey in the BRIM area (as described above).

3. A mineralization occurrence map (scale 1:1 000 000) indicating the location of mineral showings within the BRIM area has been compiled from various provincial and federal sources.
4. A map (scale 1:100 000; reproduced as Figure 7.6) has been compiled that indicates the collar locations of diamond drill and Ontario Geological Survey sonic drill holes within the BRIM area, core for which is stored at the Larder Lake and Porcupine Mining Division Drill Core Storage Libraries.
5. Colour-contoured, calculated magnetic second vertical derivative maps for the BRIM area based on digital total field magnetic survey data released in 1984 (Lovell *et al.* 1985, p.166) (scale 1:100 000) were purchased late in 1985. The calculated magnetic second vertical derivative is one example of many enhancement techniques to which digital survey data are amenable. This enhancement of BRIM magnetic data resulted in substantially increased resolution of lithologic contacts and faults.
6. In cooperation with K.D. Kalicharran, BRIM Data Geologist, an investigation is in progress concerning the potential application of remote sensing data to mineral exploration. The study currently involves interpretation of Landsat multispectral scanner (MSS) and computer-enhanced MSS data, Seasat-SAR radar imagery, and stereoscopic analysis of black and white aerial photography. Preliminary results of this work suggest that in areas of up to 90% overburden cover, computer-enhanced MSS data can be effectively used to establish regional and semi-regional basement structural trends and to differentiate between basement lithologic (e.g. intrusive versus supracrustal assemblages) and volcanostratigraphic (e.g. tholeiitic versus calc-alkalic) domains. On the contrary, aerial photography is better suited to extract basement structural trends of semi-regional to local extent and to establish the presence and effects of surficial features.
7. In cooperation with D. Guindon, Drill Core Library Geologist, Swastika, work is in progress to develop a locally accessible computerized geoscience database for the BRIM area. When operable, the system will allow the user to access cross-indexed data pertaining to Resident Geologist assessment and newspaper clippings files, core and rock samples stored at the Drill Core Storage Libraries, mineral showings, and appropriate references from scientific literature. The literature reference section of the database is currently operable and, as of December, about 800 keyword cross-referenced articles pertinent to the mineral potential of the BRIM area may be accessed via computer at Drill Core Storage Libraries in Kirkland Lake and Timmins.
8. BRIM poster displays were presented at the Matheson Fall Fair in August, at the Canadian Institute of Mining and Metallurgy Second District Three Meeting in Timmins, and at the Ontario Geological Survey Geoscience Research Seminar and Open House '85, in Toronto. An oral presentation outlining the BRIM Economic Geologist's program was also given at the Open House '85 (Bath 1985b).

ABBREVIATIONS

amph - amphibole
arg - argillite
asp - arsenopyrite
bn - bornite
carb - carbonitization
cord - cordierite
cp - chalcopyrite
gal - galena
gt - garnet
iv - intermediate volcanic rocks
mo - molybdenite
mv - mafic volcanic rocks
ser - sericitization
sil - silicification
po - pyrrhotite
py - pyrite
tell - telluride
uv - ultramafic volcanic rocks

Copies of all compilation maps as well as the calculated magnetic second vertical derivative maps are available for examination at the offices of the Resident Geologist in Kirkland Lake and in Timmins, as well as at the Larder Lake Mining Division Drill Core Storage Library, in Swastika.

ECONOMIC POTENTIAL

The potential for the Black River-Matheson area to host economic gold mineralization is excellent. Of 252 documented mineral occurrences, showings, and mines within the area (Bath 1985a, Figure 2), 198 (or 78%) contain gold as their principal commodity. Generally, a documented assay value of 0.01 troy ounce of gold per ton is the minimum criterion for a gold occurrence. Considering that more than 90% of bedrock in the area has not been intensively explored by conventional prospecting and that outcrop exposure is <10%, the real significance of the number of showings and the area's potential to host additional deposits becomes apparent. Areas particularly worthy of further exploration efforts are discussed by Bath (1985a) and below.

PROPERTY VISITS

The numbers in parentheses after the name correspond to the numbered locations on Figure 7.1.

R. ANNETT AND R. FERGUSON GOLD OCCURRENCE (1), Asquith–Churchill Townships Boundary Area

Near the southern end of a stripped area, the base of a basalt flow is irregularly banded and slightly altered; possibly, the flow incorporated some of the substrate over which it flowed. To the north is white feldspar porphyritic (possibly calc-alkalic) basalt containing feldspar phenocrysts <3 mm long, and fractured abundantly. Fractures are filled with white quartz-carbonate stringers and alteration, pyrite comprising <10% of the stringers and alteration. Farther north is a rock trench blasted into white feldspar porphyritic (phenocrysts <1 cm) basalt. North along the stripped area is fine-grained basalt with areas of steam explosion breccia <0.3 m wide. The northern extremity of the stripping is pillowed porphyritic basalt striking 320°, dipping steeply and having tops to the northeast.

About 125 m to the southwest is stripped fine-grained basalt cut by many parallel, and other orientations of, white quartz-carbonate veins, and a flow base (either that described in the first stripping men-

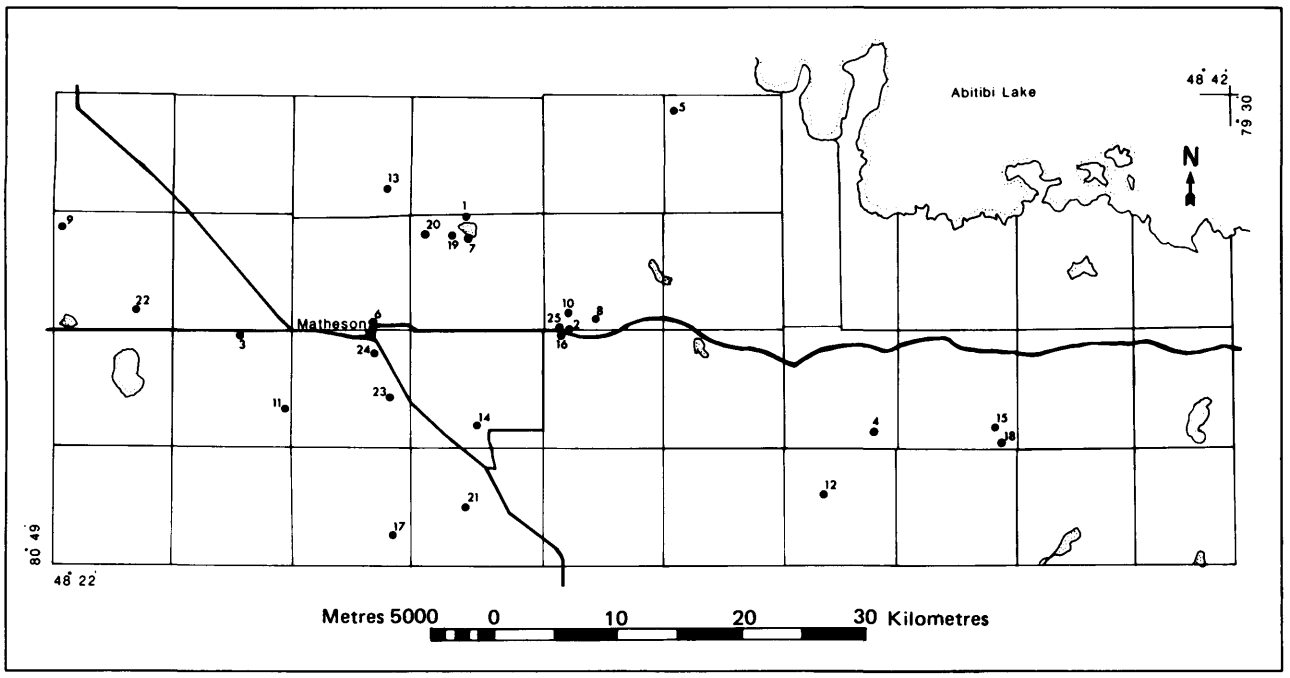

Figure 7.5 . Property Visits, 1985: BRIM Economic Geologist

tioned, or a flow below it). An interflow sedimentary source of the gold in the quartz-carbonate veins and alteration may be in the gully between the two stripped areas. Upon asssay, float in the gully yielded wolfram (Ralph Ferguson, prospector, Matachewan, personal communication, 1985).

E.A.M. ARMSTRONG GOLD OCCURRENCE (2), Asquith Township

Stratigraphy where stripped near Mosson creek is, from south to north (probably top to bottom):

Massive basalt base of overlying basalt

Sheared rusty possible interflow sedimentary rock cut by chalcopyrite-pyrite-gold-bearing quartz veins (general attitude 230°/dip steep southeast) 1 m wide

Brecciated white and green banded chert

Boudinaged banded interflow tuffaceous sedimentary rock

Sheared banded flow-top breccia

Coarse-grained flow-bottom breccia

Cherty tuff interspersed with mattress pillows

Up hill 200 m, stripping near the Tom Saville shaft exposes the stratigraphy as follows (south to north):

Medium-grained basalt

Quartz veins (attitude 085°/dip 80° north) with rusty streaks from leaching carbonate and pyrite

Quartz veined cherty tuff and other rocks fractured closely-spaced subparallel

Mixture of basalt and cherty tuff cut by rusty mafic dikes

BAY RESOURCES AND SERVICES INCORPORATED PLACER GOLD PROSPECT (3), Milligan Township

Appreciable concentrations of gold were recovered during summer 1985 by sluicing and magnetically beneficiating esker magnetic black sand and gravel that are vegetated over by Jack Pine and sparse underbrush, below which is forest floor consisting of organic debris and rusty mineral soil 0.3 m deep.

One location of gold-bearing sediments is the flank of a dry kettle depression. The gravel here has open framework (river current deposit), i.e. the fines are not greatly winnowed out (and thereby upgraded) by beach action, nor are strand terraces evident. Some placer gold grains are fine gold, others are with anhedral to euhedral pyrite grains, or with silver, or amalgamated with mercury, etc.

In one section, the black sand is indicated by a magnetometer survey to be present in an area 1200 by 200 m. Depth of the gold-bearing black sand is being determined.

B. BOLDUC GOLD PROSPECT (4), Asquith Township

Stripping by bulldozer blade followed by pressure hose has exposed glacially polished bedrock 65 m up (westward) from the west shore of a north-trending pond that is south of Speed Lake and east of Frith Lake. The northern stripping exposes, from east to west (top to bottom):

Thick bedded feldspar-sericite-quartz-chlorite rock

1 m wide thinner bedded feldspar-sericite-quartz rock

1 m wide green carbonate rock

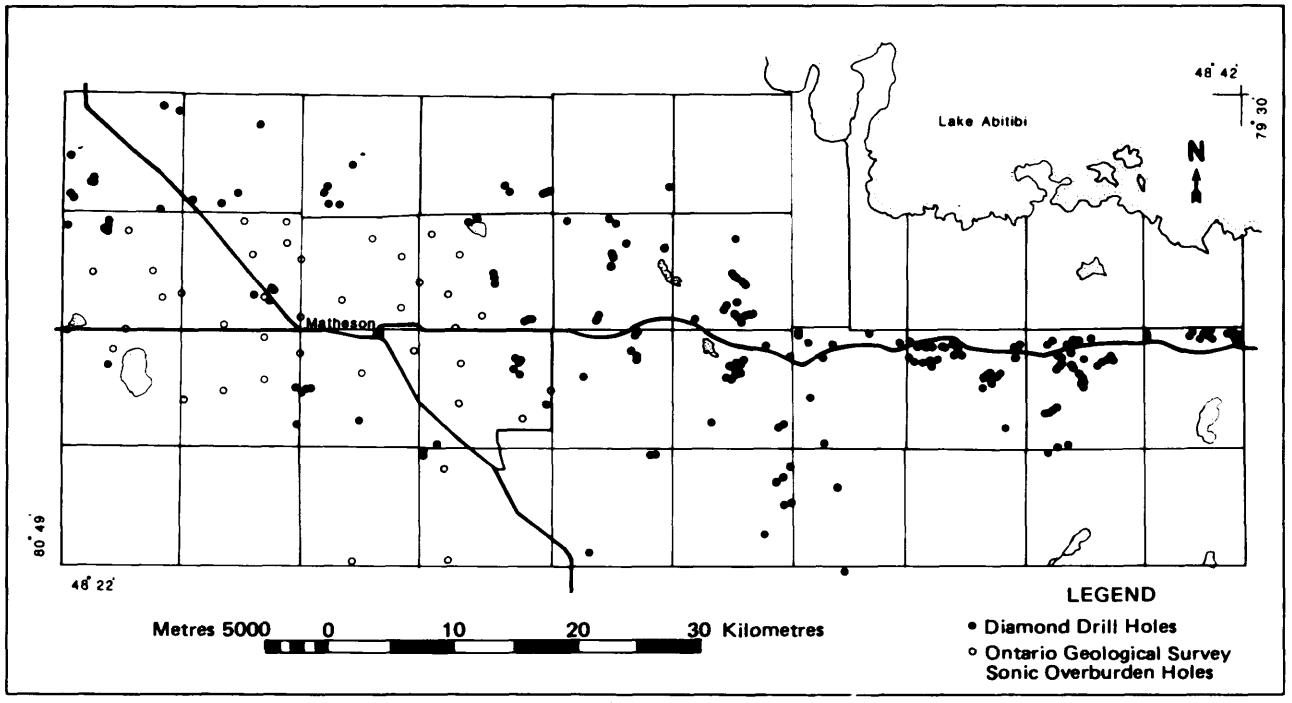

Figure 7.6 . Drill Hole Collar Location Map for BRIM Area Core Stored in the Larder Lake and Porcupine Mining Division Drill Core Storage Libraries

Massive feldspar-sericite-quartz rock that has 1 to 2 cm thick dark chilled margin and pink (hematitized) parts cut by quartz-tourmaline-chlorite veins, and in its western part contains irregularly shaped chloritic inclusions

Shaft

Basalt cliff

Present also are gabbro dikes and sills that have been carbonatized perhaps by intruding and absorbing green and other carbonate rock. The gabbro is associated with quartz that occurs as internal gash veins and also as veins emanating short distances from the gabbro. Gold is associated with quartz.

BRITISH MATACHEWAN GOLD OCCURRENCE (5), Powell Township

Claim MR 53921 main showing is in Gowganda Formation conglomerate common to the area; greenish grey matrix and many pink feldspar-white quartz (granitic and vein sources), chert, basalt and other pebbles, indicating the coarse epiclastic fraction may be rather far from source. This is not a basal conglomerate; its distance above Archean basement rocks is not known.

The conglomerate is cut by quartz veins in a zone 5 m wide, in which younger (cross-cutting) rusty quartz-carbonate veins trending 020° and dipping subvertically contain pyrite, chalcopyrite, and gold. A selected grab sample contained 0.163 ounce gold per ton (John Shirriff, prospector, personal communication, 1985). The EM 15 anomaly trends 050° through where the gold occurrence is exposed, and may be tested by an angle hole collared down hill and diamond drilled towards the northwest. If basement rocks are encountered, an attempt would be made to intersect rocks at the contact between two flows.

A 6 m wide diabase dike intruding Gowganda Formation sedimentary rocks trends 310° through several claims. Plans are to explore the dike and wall rocks at the dike's intersection with the projected extension of the gold ore zone of Matachewan Consolidated and Young-Davidson past producers. One purpose is to locate if and where their ore zones (which are in Archean basement rocks) extend under the covering Proterozoic sedimentary rocks.

DALY GOLD PROSPECT (6), Catharine Township

Rock as well as soil have been removed, long ago, in trenching that follows gold-bearing quartz veins across a northwest-trending northeast-facing cliff. West of the cliff is relatively fresh (unaltered) basalt with pillows indicating tops are to the northeast.

The cliff face is composed of stratabound sericitic black silicified rock that is largely interflow sediments. Instead of diamond drilling the quartz veins, which parallel stratification, future drilling is planned to drill perpendicular to the strata. The hole is to be collared up hill in the footwall basalt, so as to intersect the entire thickness of interflow sedimentary rock (confirmed by drilling a short distance into basalt presumed to overlie the sedimentary rock). This way the location of the upper contact of the sedimentary rock under the low ground's soil cover can be ascertained.

R. FERGUSON AND R. ANNETT BARITE AND CHALCOPYRITE OCCURRENCES (7), North Williams and Dufferin Townships

Most of the barite is in veins cutting the Cobalt Embayment's westernmost area of Lorrain Formation, both in the Lorrain Formation near where it is cut by Nipissing Diabase, and in veins cutting the diabase. Some of the barite is white, and some is reddish. Most of the Lorrain Formation is feldspathic sandstone that is relatively uniformly brownish red coloured, and contains a few sand-sized white vein quartz epiclasts and grains of magnetite.

Some of the barite is disseminated in Lorrain sandstone, and some forms subconcordant or concordant lenses and streaks. This Lorrain sandstone is feldspathic, reddish and greenish grey coloured, and contains white vein quartz pebbles, calcite, and disseminated pyrite partly replaced by chalcopyrite. In parts of a stratigraphic section exposed 3 m thick, chalcopyrite forms about 0.5% of the rock. Disseminated chalcopyrite is present in places in Lorrain orange-coloured sandstone throughout an area 0.2 km in diameter. Assays of silver have been obtained from the copper-bearing Lorrain sandstone (Roy Annett, prospector, Shining Tree, personal communication, 1985).

GOSSELIN GOLD PORSPECT (8), Churchill Township

Along the bulldozer trail 125 m from the Chief Stewart Saville gold discovery (on a small, partly stripped peninsula that juts into West Shining Tree Lake), is bedrock stripped of its soil cover. The stratigraphic section exposed is (northeast to southwest, probably top to bottom):

Pillowed basalt (tops northeast?)

Massive fine-grained basalt

Sheared chlorite-sericite-dolomite sedimentary rock 3 to 8 m thick, containing disseminated pyrite, and cut by quartz-carbonate veins roughly parallel to the contact with basalt and by gabbro sills <0.3 m thick.

More massive, less rusty less chloritic sedimentary rock that has some beds that contain lithic fragments and that are stretched to the extent of being boudinaged. Sand to silt-sized buff-coloured beds average 1 cm thick, and grey mudstone beds are 1 to 2 mm thick. Near the western limit of the exposure is gold-bearing carbonate rock containing 0.5% to 2% disseminated pyrite and cut by quartz-carbonate veins the wall rocks of which are bleached to buff colour.

On the peninsula and 30 m southwest of the main stripped area are dikes of white feldspar porphyry, parts of which have chloritoid alteration.

D. HYDE AND L. HUBERT GOLD OCCURRENCE (9), McCann Township[1]

[1]concession II, lot 2

Amphibolitized recrystallized basalt and interflow sedimentary rocks are intruded by syenitic rock. The basalt has coarsened grain sizes apparently varying directly with proximity to the metasomatic effect of syenite, and in places contains magnetite. Coarsest grained basalt has mafic minerals extending dendritically from points of nucleation. The needles of pyroxene or actinolite are a maximum of 4 cm long.

At the main showing, the metamorphosed basalt is cut by disseminated pyrite-bearing reddish syenite porphyry and syenitization and biotite lamprophyre dikes, and by bluish grey molybdenite-bearing quartz veins that contain pyrite, malachite, and chalcopyrite, and have pyrite more abundant in the wall rocks. The wall rocks contain chlorite, some of it forming slips, and a little epidote. The highest assays were 0.25 and 0.64 ounce gold per ton, with many at 0.003 ounce gold per ton, and minor amounts of silver, molybdenum, copper, zinc, and arsenic. Diabase dikes trend north and probably form part of the Matachewan swarm. Gowganda Formation conglomerate and red sandstone cover an eastern part of the claim group, around Morland Lake.

The gold mineralization resembles somewhat the Playfair Township "Arrow" past producer of Pamour Porcupine Mines Limited, and the Garrison Township "Murphy" past producer of Kerr Addison Mines Limited, although this McCann Township mineralization is deeper in the cupola of a syenite porphyry stock and consequently is in host rocks of higher metamorphic grade.

KIRKLAND BASIN GOLD PROSPECT (10), Teck Township

Newfields Minerals Incorporated diamond drilled several thousand metres through the Kirkland Lake North Break, beginning a series of 1000 m holes to test the North Break above the 3075-foot (930 m) level. Newfields Minerals Incorporated also examined the long (more than 1 km) crosscut from Lake Shore No. 5 shaft 3075-foot level station to a short distance above the base of the Timiskaming Group. Much of what appears on old maps as intrusive rocks (e.g. syenite, syenite porphyry, or quartz-feldspar porphyry) are trachytic extrusive rocks, and debris flows and other sedimentary rocks.

LAKE SHORE MINES LIMITED GOLD PRODUCER (11), Teck Township

Since Lake Shore Mines Limited was put back into production in 1983, mining is trackless, being on upper levels accessible for scoop trams via a decline ramp, and using jumbo drills and a mining method perfected in France. Plans are to use this method for ore accessible via Lake Shore No. 5 shaft.

The mining method consists, in part, of repeatedly mining out a drift face 4 m high (as much as 12 m wide in upper levels), then covering the drift floor with sand 0.3 m thick, laying plastic sheeting over the sand, backfilling with concrete, and (after the concrete is cured) mining underneath. The cement backfill pipe is not clogged by this process because it is in the sand on the drift floor. The concrete is reinforced every 0.6 m, at angles that constitute the best pattern, so this mining (including stoping) method might serve down to the bottom level of 3950 feet (1200 m) of Lake Shore Mines Limited's active vertical shaft No. 5, if exploration outlines adequate ore reserves.

MAUDE LAKE GOLD MINES LIMITED GOLD PROSPECT (12), Beatty Township

From 1917 to 1920 a decline shaft was sunk, with levels at 100 and 200 feet (lateral work totaling 470 feet), and a 50 tons per day mill was built. In 1946 and 1947, Sylvanite diamond drilled 20 000 feet. For the past five years, a sustained program of exploration has been carried out, financed privately. The program has included diamond drilling, stripping of Great Clay Belt glacial lake bottom soil and underlying till, and rock work from which (in 1984) a bulk sample of 1000 tonnes was sent to a custom mill and (in 1985) 15 000 tonnes were passed through a sampling tower. Subsequently, the bulk sample from the sampling tower (about 3 tonnes) was analyzed.

Strata strike northwest, and include a komatiite (magnesium-rich ultramafic) flow to the northeast (top), underlain by sulphide-rich interflow sedimentary rock in places carbonaceous, underlain by flow top breccia or welded tuff (contains rounded fragments, some of which have selvages), underlain by a pillow-topped tholeiitic basalt flow. The tholeiitic basalt has some pillows rimmed by massive sulphide mineralization, and is altered and cut by gold-bearing quartz-carbonate veins.

These veins are transitionally white to greyish black, and contain marginal and disseminated carbonate (weathers rusty buff coloured), and are flanked by wall rock alteration. Most gold is in pyrite, although some is refractory in arsenopyrite; gold concentrations vary as to the amount and type and nature of vein quartz (R. Bennett, Consultant Geologist, Sudbury, personal communication, 1985).

MONCRIEFF GOLD PROSPECT (13), Catharine Township[1]

[1]concession III, lot 5, north half

Rocks including "green carbonate rock" (green mica, sericite, chlorite, dolomite, quartz, siliceous laminae, pyrite) are cut by quartz-tourmaline veins. Rocks stratigraphically above and below (respectively to the east and west) are basalt flows. Where subparallel to each other and the flows, gold-bearing carbonate veins may represent recrystallized and subsequently sweated-out siliceous beds, or else some of the silica came from pyroxene or olivine of the basalt that flowed over a carbonate-rich interflow sediment. Diamond drilling is planned that will cross-section the contact zone between flows, from hanging wall to footwall.

NEELANDS-THOMPSON GOLD OCCURRENCE (14), Asquith Township

Bedrock types are green carbonate, basalt, syenite porphyry, intrusive and fragmental quartz-feldspar porphyry, and carbonate-quartz-pyrite (fine-grained)-chromium muscovite rock. Six feet (almost 2 m) of the latter rock contained 0.16 ounce gold per ton (6 g per tonne) according to Ralph Ferguson (personal communication, 1985). The syenite porphyry consists largely of reddish feldspar phenocrysts in a matrix of chlorite and pink feldspar, and resembles porphyry at Young-Davidson past producer that was mined there for its disseminated as well as quartz vein content of gold. Another rock type here that elsewhere contains gold and could be followed by geophysics, stripping of soil, and diamond drilling is quartz-sericite-pyrite (e.g. 2%) schist.

PACESETTER GOLD OCCURRENCE (15), Churchill Township

Rock types present in diamond drill core around the drill sites are basalt, rusty carbonate rock, and sericitic-quartz "eye"-white feldspar rock. Core from carbonate rock and quartz-carbonate veined rocks was split. Assays obtained a maximum of 0.2 ounce gold per ton according to prospectors Roy Annett and Ralph Ferguson (personal communication, 1985), who think that the zone may extend through Oddur Lake to Ian Lake.

F. AND P. RIVARD AND L. RAITANEN GOLD OCCURRENCE (16), Eby Township[1]

[1]concession IV, lot 2, south half's southwest quarter

Polymictic conglomerate (pebbles of quartz, basalt, rhyolite, sulphide mineralization, argillite and so on) has open framework, although coarse epiclasts form 30% of the rock. Some imbrication is present. Interbeds are irregularly banded chlorite-feldspar-carbonate-sericite rocks. The environment of deposition may have been shoreline (beach or eroded delta).

Syenitization is evident from the presence of hematitization (reddening) and lamprophyre dikes. Stratigraphically below (to the southeast) is sulphide facies iron formation presumably deposited in an offshore (littoral) reducing or deep water (euxinic?) environment. Transitional between deltaic and offshore environments, shallow shelf gold-accumulating sediments should be present if the environment was not changed suddenly (e.g. by volcanic or seismic activity).

C. SHEA GOLD OCCURRENCE (17), Maisonville Township

Volcanic flows are iron-rich tholeiitic basalt of the Kinojevis Group, which filled an original basin extending from Matheson to Kirkland Lake, Ontario, and eastward to Malartic, Quebec.

The Kinojevis Group never hosted a successful gold mine until the Harker-Holloway Townships discoveries being currently developed, despite Maisonville Township having more gold occurrences on the Timmins-Kirkland Lake Map 2205 than any other township. One deterrent to discovery of mineable gold is scarcity of (or failure to find) gold-bearing interflow sedimentary rock. Another problem is that diamond drilling tended to be directed to intersect native gold-bearing white quartz-carbonate veins and pyritized wall rocks at right angles. Most veins fill cooling fractures roughly perpendicular to flow contacts, and are only as long as the flow is thick, presumably having steamed up from what the basalt flowed over. Most flows are 30 to 150 m thick. In contrast, substantial ore zones in the general area are in shears and interflow sedimentary rocks subconcordant to concordant with stratigraphy and of considerable extent along strike and down dip.

Therefore, future diamond drilling might be directed perpendicular to stratification.

Tops are to the east. Upper parts of flows are distinguished by pillows and below them varied texture (i.e. areas of massive white feldspar containing acicular mafic mineral) in an overall matrix of medium-grained basalt. Deeper parts of flows are more uniform medium-grained basalt.

Carbonatization occurs as streaks trending east, perpendicular to flow contacts, and is characterized by white median quartz-carbonate veins averaging 1 cm wide, subparallel and closely spaced. Wall rocks are bleached (carbonatized) and contain disseminated pyrite associated with gold.

Pink and grey feldspar porphyry dikelets are characteristic late differentiates of tholeiitic basalt, and rarely contain much gold although larger bodies of this type of porphyry can heat-pump pre-existing gold into traps. Gas vesicles in a porphyry dike indicate it was intruded when load pressure on the flow was not great.

RECOMMENDATIONS FOR EXPLORATION:

As a result of gold discoveries at Hemlo, in Harker-Holloway Townships by Barrick Resources Corporation and Canamax Resources Incorporated; and in Ligneris, Casa Berardi, and Estrades Townships in Quebec by Vior Mining Exploration Company Incorporated, Inco Limited and Teck Corporation respectively, thousands of mining claims have been staked along the contacts between volcanic and sedimentary rocks crossing the Ontario-Quebec Boundary. Features characteristic of most gold ore zones are the following:

1. Gold ore zones occur along the contacts of volcanic with sedimentary rocks, both the contact of a large belt (or remnants of a large belt) of volcanic with a large belt of overlying sedimentary rocks, and alternately along sedimentary rocks within predominantly volcanic terrane.
2. Conglomerates and related grey wackes are within 1 km away along strike.
3. Sources for the gold ore host sedimentary rocks (and sediments absorbed into and thereby altering and imparting a foliated appearance to overlying flows, most of which are tholeiitic and komatiitic basalt) are mainly subaerial edifices of calc-alkalic volcanoes such as described by Rocheleau and Dimroth (1985). In the Larder Lake Mining Division, erosion of the calc-alkalic Skead Group provided sediments for the Larder Lake (Kerr Addison gold producer) area sedimentary rocks; similarly, the Halliday Township calc-alkalic dome supplied most of the sediments west of Matachewan; and erosion of topographically high land where now occupied by upper Lake Abitibi trondhjemite-tonalite rocks supplied most Matheson-to-Holloway Township sediments.
4. Most gold ore is in concordant linear bedrock topographic lows, probably resulting from the susceptibility to erosion of stratabound "shear zone" interflow (clastic and pyroclastic sediments, chemically cemented) sedimentary gold ore's gangue minerals sericite, pyrite, carbonate, "graphite", etc. Within the linear bedrock topographic lows, however, the best ore can be relatively high bedrock topography (because of high silica content) compared to submarginal ore.
5. Gold ore is in magnetic lows (partly because magnetite was converted to hematite, pyrite, etc.) within magnetically high regions. Many of these magnetic lows parallel stratigraphy.
6. Dips of gold ore zones typically flatten at depth (tending to "migrate" down dip onto neighbouring claims) perhaps because of original delta apron slope.
7. Gold ore zones plunge east or west roughly along strike (concordant to subconcordant with stratigraphy), perhaps because of steepening the dip of the delta apron's original arcuate shape.

The great majority of gold mining discoveries were made by basic prospecting of bedrock topographic highs (outcrops), which expose an average of <5% of total bedrock surface. In contrast to outcrops, zones anomalous in gold tend to be bedrock topographic lows covered by overburden, such as under muskegs or, in the words of Harry Oakes before he discovered the Lake Shore gold mine (produced 8.5 million ounces of gold) at Kirkland Lake, "Everyone knew that the richest ore is under the lakes in this country" ("Lake Shore" *in* The Northern Miner, March 6, 1952). Therefore, "rules of thumb" to quickly zero in on and thereby accelerate the frequency of gold discoveries are the following:

a) Detect rock type contacts by magnetic surveys, e.g. helicopter-borne gradiometer.

b) Identify the topographically lowest bedrock that is concordant with strata by estimating overburden thickness, which can be done by interpreting electromagnetic surveys (Pitcher 1985) and by compiling water well, overburden drilling, and diamond-drill hole casing information such as on Data Series and Geological Data Inventory Folio maps of the Ontario Ministry of Northern Development and Mines and its predecessors.

c) Diamond drill these coincident bedrock topographic and magnetic lows, spotting follow-up holes guided by the sedimentary rock's environment of deposition (along strike basinward from the greywacke towards the chemically cemented fine-grained sediment, which now is quartz-sericite-pyrite + carbonate schist, but not as far offshore as the turbidites).

Where "porphyry" syenitic rocks (which originated by volcanic and sedimentary rocks subsiding until they partly melted, according to Jensen and Langford 1985, p.35 and 95) intrude through gold ore zones such as described above, they heat pumped ahead of them (e.g. Pamour "Arrow" and Kerr Addison "Murphy" past gold producers) and/or incorporated into themselves (e.g. in cooling fractures, in the case of Kirkland Lake gold ore) pre-existing gold ore zones they remobilized.

ONTARIO GEOLOGICAL SURVEY ACTIVITIES

PRECAMBRIAN GEOLOGY SECTION

L.S. Jensen continued synoptic mapping of the Kirkland Lake and Larder Lake areas; part of a multi-year program to remap a 24-township area in the Archean Abitibi Subprovince. The 1985 field season focused on the geology between the Round Lake Batholith and the Kirkland Lake-Larder Lake Fault zone.

R. Johnstone and N.F. Trowell continued mapping in McCool, Hislop, Guibord, and Michaud Townships as part of a program to carry out detailed, synoptic, and stratigraphic mapping along the Destor-Porcupine Fault from east of Timmins to the Quebec border (BRIM).

ENGINEERING AND TERRAIN GEOLOGY SECTION—GEOPHYSICS/GEOCHEMISTRY SECTION

C.L. Baker, M.B. McClenaghan, and K.G. Steele did a reconnaissance heavy mineral and geochemical backhoe sampling project of the Munro Esker. Sampling took place in an eight-township corridor which straddles the esker from Michaud Township in the south to Kerrs Township in the north. A total of ninety-six 8 to 10 kg samples were collected from 2 to 3 m deep trenches (BRIM).

C.L. Baker, K.G. Steele, and M.B. McClenaghan continued the reconnaissance till sampling program in the Matheson-Lake Abitibi area. In 1985, 241 till samples were collected from 312 backhoe trenches and 60 sonic drill holes totaling 2595 m were drilled (BRIM).

GEOPHYSICS/GEOCHEMISTRY SECTION

D.H. Pitcher evaluated the effectiveness of electromagnetic measurements in deriving electrical conductivities and thickness of multi-layered Quaternary stratigraphy. The overburden sonic drill hole logs were used in conjunction with the airborne data released in 1984 and the combined EM-31/EM-34 instrumentation results (BRIM).

MINERAL DEPOSITS SECTION

D. Long and A.C. Colvine continued studies of the Huronian Supergroup designed to evaluate sedimentological controls on placer gold deposits. Studies in 1985 concentrated on completion of preliminary maps of Huronian strata in Sheard, Ogilvie, Amyot, Browning, Hodgetts, Unwin, Lampman, and Leask Townships; and adjacent parts of North Williams, Dufferin, Stull, and Valin Townships.

J. Malczak investigated the Maude Lake Gold Mines Limited gold deposit in Beatty Township (BRIM).

J. Malczak studied the industrial mineral potential of the Black-River Matheson area. The most significant possible sources (excluding asbestos) are: serpentine filler minerals from the Hedman Mine in Warden Township; alkali feldspar flux minerals from a hornebleńde syenite phase of an intrusion in Egan Township; talc-magnesite from a peripheral zone at the former Johns-Manville Munro Asbestos Mine in Munro Township; and monument/facing stone from the Garrison stock in Garrison Township (BRIM).

D.G. Troop studied the geology and metasomatism at the Ross Mine and vicinity (BRIM).

P.J. Whittaker continued the metallogenetic studies of the Black River-Matheson area by doing detailed mapping of the Croesus and White-Guyatt deposits in Munro Township, in west-central Thackeray Township and northeastern Harker Township (BRIM).

BRIM (Operation Black River-Matheson), funded equally by the Ontario Ministry of Northern Development and Mines and the Ontario Ministry of Natural Resources, is a multi-year geoscience program which covers a 40-township block straddling Highway 101 east of Timmins (Night Hawk Lake) to the Ontario/Quebec Border. The objectives of this program are to provide a comprehensive and integrated geoscience database; to develop a regional stratigraphic and metallogenetic framework; and to promote new mineral exploration strategies and development in the BRIM area.

RESEARCH BY OTHER ORGANIZATIONS

GEOSCIENCE RESEARCH GRANT PROGRAM

McMaster University

8. Cobalt Resident Geologist Area, Northeastern Region

Leo Owsiacki

Resident Geologist, Ontario Ministry of Northern Development and Mines, Cobalt

INTRODUCTION

Although commodity prices remained at depressed levels in 1985, a certain degree of stability, absent for the past decade, returned to the marketplace. Silver was the most important commodity produced in this area and closed out the year at U.S. $6.12; a drop of 13% from a year earlier. This drop fairly accurately reflects the overall trend in mining and exploration in this area during 1985. Both activities declined marginally from last year but remained at relatively high levels.

Two new developments in the Cobalt camp include the recent discovery of a new outcropping of a high-grade silver vein and renewed exploration of Sulpetro Minerals Limited's large land holdings by Canadaka Mining Corporation. In addition, Silverside Resources Incorporated and Silver Lake Resources Incorporated are in the final stages of decline construction at their Lorrain Township Silver Occurrence and should reach the inferred ore zones during the Spring of 1986.

Exploration and development of the area limestone and dolomite reserves expanded at a rapid rate, primarily due to hopes that a new pellet fluxing project, being developed at two local iron mines, will require local material.

Gold exploration activity in the Temagami greenstone belt continued to increase as a number of large companies acquired ground and initiated modest exploration programs during the year.

Negative developments for the area include the recent appeal by the Temagami Indian Band, of a ruling made in favour of the Provincial Government last year, regarding resolution of a long-standing land claim. This claim has effectively stifled exploration for the past decade. The appeal will, no doubt, result in a continuation of the Land Caution for some time to come. In addition, Silver Century Explorations Limited and Agnico-Eagle Mines Limited have given up, for now, on the old King Edward Mine and recently pulled the pumps. The mine workings were dewatered in 1980 and intensively explored since this time. In March, the Langis Mine was downgraded from producer to an exploration-only basis. Further, Agnico-Eagle Mines Limited reduced their area work force by virtually 50%.

The many research projects initiated in the past few years are continuing and several new projects, funded by SPARC (Special Projects Assisting Resource Communities) have recently been started by this office. They are described in more detail in the following section. These projects are aimed at expanding the local economic base and providing new data to assist in finding and developing new commodities and at expanding our knowledge of the geology and ore forming processes in the camp.

RESIDENT GEOLOGIST'S ACTIVITIES

During the year, the Cobalt office was staffed by Leo Owsiacki, Resident Geologist, and contract personnel including P. Anderson, Resource Geologist; K. Larabie, Secretary; C.D. Van Leeuwen, Secretary; R. Larsen, Contract Geologist; W.T. Grant, Contract Geologist; E.M. Dodd, Contract Geologist; L. Francis, Draftsman; A. La Bine, Geological Assistant; M. Gabbani, Junior Assistant; A. Marvin, Junior Assistant; A. Conti, Experience '85 student, and B. Mercier, Experience '85 student.

Two programs were proposed and supervised by office staff under the auspices of the Canada Works-Section 38 and Ontario Resource Sector Program. Seven men were hired over a three-month period to clear township boundary lines, mine roads, and two sites for a mining and tourism project. The two tourist sites were also landscaped by fencing of mine stopes, building of viewing platforms, parking lots, trails, and picnic tables.

The compilation and publication of Geological Data Inventory Folios (GDIFs) was continued during the year. Fourteen folios were completed and published in 1985, and three are currently in press. In the past two and one half years, GDIF's for a total of 47 townships have been published, representing 58% of the Cobalt Resident Geologist's area. The remainder of the area should be completed by the Spring of 1987.

Technical assistance and consultative services were provided to prospectors, industry representatives, geologists, government, and the general public as a means of encouraging and facilitating effective exploration and development in the area. Numerous field trips were conducted for university, industry, and government representatives. These trips are important in introducing new companies to the exploration potential of the area and in educating those not familiar with the local geology. In addition, lectures were presented at local schools at varying levels by the office staff and a field trip and lecture presented to the Ministry of Natural Resources Junior Ranger camps in the Temagami District.

A number of potentially hazardous areas near Cobalt were inspected with representatives of the Ministries of Labour and Natural Resources, and recommendations for remedial action presented.

The Resident Geologist continued a regional and structural study of Archean basement rocks and their mineral potential in the area extending from Temagami north to New Liskeard. Detailed mapping and sampling of a volcanic inlier situated in Banting Township (Owsiacki 1984) was extended to the east into Best Township.

In Butler Township, a minor new gold occurrence was discovered on claims held by Kyanite Mining Corporation during a recent property visit of kyanite showings in the Grenville. A sulphide-stained outcrop

was observed and sampled, and returned a value of 0.41 gram of gold per tonne. The unit extends over a wide area and is comprised of a pyritiferous (3% to 10%), schistose, grey, altered quartzite. The gold is apparently not associated with any veining. Subsequent grab samples from a few widely separate locations provided minor but still anomalous values of 0.07 gram of gold per tonne and 0.21 gram of gold per tonne. The unit is interbanded with coarse-grained kyanite-garnet gneiss, appears uniformly mineralized with pyrite and extends over a large area. It was additionally noted that pyrite concentrates in narrow to massive lenticular pods in surface outcrop and both copper and silver values were previously noted in drill core. Because of these factors, the few grab samples with their anomalous gold values are believed to be significant. No other similar mineral occurrences have been recognized within 100 km of this area.

Use of the facilities and services provided by the Resident Geologist's Office remained at a fairly high level in 1985, but will probably decline moderately in 1986 with declining exploration. Additional programs being carried out by office staff include the following:

ECONOMIC EVALUATION OF THE LAKE TEMISKAMING PALEOZOIC OUTLIER by W.T. Grant

A project was recently initiated through this office to evaluate an extensive area of Paleozoic cover, from an economic perspective, in order to assess its mineral potential. The outlier is exposed near its southern boundary at Haileybury, trends northwest to Englehart, and occupies part of the Province of Quebec, east and south of Lake Temiskaming. Its maximum width in Ontario is approximately 14 km but only a limited portion is exposed through the thick deposits of glacial clay which overlie most of the region.

Initially, the project involved grab sampling and surface sampling of outcrops (using a J.K.S. Packsack® drill). In those areas drilled, a maximum of 3 m of core was recovered. Samples are now being analyzed for major and trace element content to establish a data base which will be used to identify those areas with the highest industrial mineral potential. Diamond drilling will be undertaken in the Spring of 1986 to establish thicknesses of formations and geochemical continuity within and along specific horizons. Additional parameters to be investigated include the suitability of the material for aggregate, concrete, and ashphalt uses and depth to bedrock, in order to define only those areas amenable to quarrying.

Limestone and dolostone from this region have potential uses as agricultural fertilizer, flux in metallurgical processes, environmental control, building stone, and as filler in paints, plastics, paper, etc.

MINING AND TOURISM PROJECT by E.M. Dodd

A self-guided tour of various historical mine locations in the Cobalt silver camp has recently been initiated by this office and funded by SPARC (Special Projects Assisting Resource Communities). Thirteen historically significant sites have been selected as potential stops on the tour. Two of these sites are currently under development and nearing completion. Each site will be identified in a brochure and accompanying map and will have a viewing and rest stop area, in addition to point-of-interest signs designating historical and geological features. Large highway billboards and numerous directional signs will assist in promotion of the tour. The tour will be partially operational in 1986 and, with continuous work planned for the coming summer, should be completed by the Summer of 1987. It is hoped that it will attract visitors to the region, thereby increasing area tourism and bolstering the local economy.

TAILINGS INVENTORY PROJECT by P. Anderson

A survey of all mill tailings in the Cobalt camp was carried out over the past year. The research included an extensive literature search investigating the historical uses of each mill and the extraction methods utilized, annual report statistics, company reports, and interviews with former mill planners, managers, and workers. Individual tailings sites were studied and described in detail. Surficial mapping was carried out at each site at a 1:2000 scale to define accurate tailings boundaries and surface features which might affect future mining and milling. Some previously mined tailings, including the Cobalt Lake and the Chambers-Ferland sites, are highlighted. The use of some tailings areas as building sites, recreational sites and for re-vegetation experiments are also reported. The report and maps have been completed and will be published by the Summer of 1986.

CORE LIBRARY by P. Anderson

In July, 1985, a building was leased in North Cobalt to replace the previous Cobalt Resident Geologist's Core Library, which was destroyed by fire in March, 1984. The building has been upgraded and includes a field office. Three sets of core racks were built, and 6506.7 m of core (73 drillholes) from 13 companies have been donated to the library and stored. A further 5000 m of core have been promised but not yet collected. A catalogue, produced with computer data processing, is currently being developed and will be available in the Spring of 1986. The building can house approximately 25 000 m of core and additional racks will be constructed in 1986.

MINING ACTIVITY

Despite a continuing decline in silver prices, suspension of three small mining operations active in 1984, and a significant reduction in Agnico-Eagle's area work force, silver production from the camp decreased only marginally from last year. This was due primarily to milling of stockpiled ore and increased grade and production of ore mined at the Castle Mine in Gowganda.

Production at Sulpetro Minerals Limited's tailings mine was not renewed as planned in 1985 because of lower silver prices. At the Silver Queen Mine, operated by Starlight Energy Corporation, mining ceased in the Fall of 1984. No recent activity has been noted at this site and milling of stockpiled "ore"

has not been carried out. In Gowganda, a small silver mine operated by Manridge Explorations also ceased production in 1984, due to depletion of ore and low silver prices.

Mining and exploration at the King Edward Mine by Agnico-Eagle Mines Limited and Silver Century Explorations Limited was terminated at the year end because of the lack of any new discoveries.

The development of the Silverside Resources Incorporated silver property in Lorrain Township continued throughout the year. A decline ramp was extended for a distance of 665 m and should reach the inferred ore vein systems in the near future. Underground exploration drilling was started during the fall to test for possible vein extensions of surface defined veins.

Quarrying by Dymond Clay Products Limited continued on a seasonal basis from May to December. Production of metallurgical limestone should reach full capacity in 1986.

Although the parent, Dofasco Incorporated, continued to operate with significant profits in 1985, the Sherman Iron Mine was closed for the fourth consecutive year for a five-week period. Production, as a result, was maintained at 1984 levels.

Only one area mill operated in 1985. Agnico-Eagle's Penn Mill continued throughout the year with all feed originating from local mines owned and operated by the company. The mill is, however, scheduled to be shut down for a four-month period beginning in December, 1985. Although no major improvements were made to the mill during the year, an addition of four cells to the floatation circuit and accompanying modifications to other segments of the mill has been proposed for 1986.

The Agnico-Eagle Mines Limited refinery operated on a continuous basis throughout the year. Modifications are currently in progress at the site and include construction of a new building to house a slag regrind mill and an arsenic distillation furnace. In addition, an oxygen injection system has been proposed for the cyanide leach circuit to increase extraction efficiency and decrease reagent costs. The refinery will be shut down for an approximate four-month period beginning in December, 1985.

Caral Minor Metals Limited, a new company formed to develop a custom roasting facility at the Cobalt Refinery site in 1984, ran into unexpected problems in 1985. As a result little, if any, work was carried out at the plant and it appears to have ceased operations entirely. A film ash operation, also located on the Cobalt Refinery site, discontinued operations in 1985.

Mineral commodities mined and paid for during the year decreased marginally from levels reached in 1984. Approximately 1 650 000 ounces of silver were produced from four area mines, representing a 5% decline from the 1 735 359 ounces produced in 1984. Iron pellet production was maintained at the 1984 level of 1 018 297 tonnes. Significant production gains were made, however, in industrial minerals. Metallurgical limestone production increased by 237% to 6000 tonnes and agricultural grade limestone production by 730% to 2000 tonnes from the previous year. Quarrying of decorative building stone increased by 94% to 258 tonnes. In addition, substantial quantities of sand and gravel were extracted. Cobalt, copper, and nickel were mined together with silver but not recovered.

KING EDWARD MINE (SILVER CENTURY EXPLORATIONS LIMITED AND AGNICO-EAGLE MINES LIMITED)

This mine was de-watered in 1980 and has been extensively explored since this time. Although a number of new veins were discovered, only the #268 resulted in any production. Ore originated primarily as drift and raise muck within a shoot of very limited extent. Total production from the mine comprised 411 tons grading approximately 20 ounces of silver per ton. This material is presently stockpiled on surface at the mine site. Mining and exploration were confined primarily to the bottom (1065-foot) level of the mine workings. Underground exploration diamond drilling during the year totaled 3831 m, representing a drop of 49% from the previous year.

Veins are located beneath the lower contact of a Nipissing diabase sill, and cut Archean mafic volcanic flows. The limited ore produced originated from that part of the vein immediately beneath the lower diabase contact.

Despite the presence of three other veins with remaining minor silver reserves, the company decided to abandon further mining and exploration at this site, for the present. Pumps were pulled in November and the mine was allowed to flood.

LANGIS MINE (AGNICO-EAGLE MINES LIMITED)

Although a new "orebody" was discovered in the Fall of 1983, subsequent development has been delayed due to depressed silver prices. Production activities at the mine were suspended in mid-March of this year for this reason. Tentative plans have been made to restart mining operations in the Spring of 1986.

In the first quarter of operations, mining was restricted to three veins. The #35-103, developed from the fifth level of the #3 shaft, was mined-out and produced 130 tons of ore grading 7.7 ounces of silver per ton of a total 1671 tons mined during the life of the vein. This represents 4% of the Langis Mine 1985 production. On the same level, 600 tons of ore, grading 11.8 ounces of silver per ton, were removed from the #35-107 vein (19% of this year's production). Seventy-seven percent of silver produced originated as development muck from the new discovery vein, #64-110, accessed from the fourth level of the #6 shaft workings. Twenty-four hundred tons of ore, grading 5.5 ounces of silver per ton, were mined in the first three months of the year from this vein. The latter two veins still contain ore and will be mined in the future.

Drifting and cross-cutting activities were limited to approximately 94 m of development on the sixth level of the #6 shaft, to access the #64-110 vein.

With the suspension of mining in March, the work force was reduced and the mine returned to an exploration only basis. Underground exploration dia-

mond drilling declined by 30% from the year earlier period to 6963 m.

All ore shoots occur within steeply dipping carbonate veins which cross-cut Huronian-age pebbly wackes. These sediments represent a thin remnant of Huronian rocks sandwiched between underlying Archean mafic volcanic rocks and the overlying base of a Nipissing diabase sill. The style of veining in the new #64-110 vein is characteristically developed in the thinly-laminated argillites, typical of the Coleman Member sediments elsewhere in the camp. Rather than a single vein, numerous, short, parallel and discontinuous veinlets and accompanying random fractures, coated with native leaf and plate silver are dominant. Mineralization is slightly different, in that argentite comprises approximately 30% of the ore and native silver the remainder. The advantage to this style of veining is the possible development of very wide, good grade stopes.

BEAVER-TEMISKAMING MINE (AGNICO-EAGLE MINES LIMITED)

Silver mining, exploration, and development continued throughout the year, although activities drastically declined as of April, 1985. At this time, the mine work force was reduced by 40% to 50%.

Mining during the year was restricted to three primary vein systems. Fifty percent of the ore was obtained from the #37 vein, above the 1330-foot level. Thirty-five percent originated from the #41 vein, and fifteen percent from the #44 vein; again both from above the 1330-foot level. In all, 22 188 tons of ore were mined with an average grade of 11.8 ounces of silver per ton. All ore was hoisted via the Temiskaming shaft. The Beaver shaft is now primarily used for ventilation.

Underground exploration diamond drilling reflected the general downturn in activity and declined 17% to 7097 m. The bulk of exploration was carried out in the northwestern mine workings (Brady Lake area) from the 1600-foot level. Drilling in this area last year encountered one good ore grade intersection. As a result, a crosscut was driven to this location and subsequent drifting along new veins carried out. Drilling in this vicinity in 1985 was encouraging enough to warrant development of an incline from the 1600-foot level to the 1445-foot elevation, where approximately 24 m of drifting were completed. A total of 134 m of drifting and crosscutting were carried out during the year in this part of the mine workings.

As a result of declining reserves and lower silver prices, the mine will concentrate on development and exploration in 1986. Mining will continue at a much reduced level.

All stopes have been developed in veins cutting Archean mafic volcanic flows below a significant, step-like structure formed at the lower contact of a Nipissing diabase sill (Robinson 1984). The new area of exploration (Brady Lake) differs in that veins occur closely related to a wide band of black, cherty interflow sediment.

SHERMAN MINE (DOFASCO INCORPORATED AND TETAPAGA MINING COMPANY LIMITED)

For the fourth consecutive year, this relatively low grade iron mine was shut down for a 5-week period in 1985. As a result, iron pellets produced remained at a level of approximately 1 018 297 tonnes, recovered from 3.98 million tonnes of crude ore. In addition to the slowdown, the work force was reduced during the year by 10%.

Although production remained relatively constant, mining of waste declined by 44% to 2.84 million tonnes. Three pits were utilized during the year. Sixty percent of the ore was mined from the East Pit. This pit is characterized by an elongate shape and has been developed to the third bench. The first bench was completed in 1985 to the eastern boundary and the second bench extended three quarters of the way across the pit. Thirty percent of the ore was mined from the central portion of the West Pit and ten percent from the South Pit. Mining of the latter pit is more or less a scavenging operation, with remaining ore in the pit removed by backhoe. The new Turtle Lake Deposit is currently being stripped and initial mining projected to begin in mid-1987.

EXPLORATION ACTIVITY

Despite a poor year for mining companies in general and considerably depressed commodity prices, exploration in this area maintained the relatively high levels reached in 1984. Although underground exploration diamond drilling decreased by 24% from the previous year to 18 833 m, surface drilling increased by 46% to 10 915 m. Combined drilling decreased only 8% from 1984 (Figure 8.2). This decline can be directly related to the mid-year slowdown instituted by Agnico-Eagle Mines Limited. Claim staking activity remained at a relatively static modest level, as it has since the enforcement of the Bear Island Indian Caution in 1978.

Emphasis was once again on precious metals exploration and although silver was, as expected, the most sought after mineral, gold exploration, particularly in the Temagami area, showed a marked increase from previous years. Exploration for limestone and dolostone began in earnest when local iron mines indicated that they may require up to 200 000 tonnes/year of this material for use in a proposed new pellet fluxing plant at the mine sites.

The most significant discovery of the year was made during the fall by two weekend prospectors from Wisconsin. Using a metal detector to search for silver float in the general Cobalt camp area, the two men discovered a surface exposure of a new high grade, silver vein in upper contact Nipissing diabase.

Major exploration and development undertaken during the year is summarized below and in Table 8.2.

T.T.L. Minerals Limited concluded a detailed mapping and sampling program at the underground workings of the old North Cobalt Shaft (Owsiacki 1985a) in Bucke Township. Records describing these workings were previously very incomplete and have been extensively updated as a result of this project. The mine produced a small amount of silver in 1909

(Thomson 1960). Four levels were mapped and a winze on the bottom level, 135 feet below the collar, identified. Two distinct, relatively parallel vein structures were recognized, along with numerous, weaker, subsidiary structures. The "shaft vein", where silver was originally mined via a short raise to surface is a typical dilatant vein (Owsiacki and Lovell 1984). Silver is developed in an erratic shoot within a vein cutting Coleman Member quartzite and pebbly wacke, immediately above the Archean unconformity. The basement rocks are comprised here of sulphide-rich, interflow cherts, quartz-eye rhyolite (?) and a feldspar-quartz porphyry intrusion. A shallow, northeast dipping fault occurs along this unconformity and contains silver where it intersects the vertical ore vein. Subsequent sampling of the vein in this area provided numerous good grade values over narrow widths.

The second, parallel structure, located approximately 15 m north of the "shaft vein" and representative of a shear vein (Owsiacki and Lovell 1984) is exposed on the bottom two levels within Archean mafic volcanic flows. Sporadic erythrite was visible along its length and sampling of the vein revealed relatively low quantities of silver (0.1 to 1.0 ounces of silver per ton over 0.5 m).

Four short holes were drilled near the shaft in the summer to test for a possible extension of the north shear vein up into the Huronian sediments and possible strike extension of the "shaft vein". The structures were intersected but returned only minor silver values.

Two additional holes were drilled in the eastern limits of the claim group to test a VLF conductor identified in 1984. No significant mineralization was encountered during this drilling.

Problems with the surface rights holder of part of the claim group resulted in termination of work following the drill program.

Osisko Lake Mines Limited acquired a four-claim group in Lorrain Township and carried out a comprehensive exploration program for silver on this ground. The claims are centred over the inferred extension of the McKenzie Fault which abuts against the new Silverside Resources Incorporated silver discovery, located approximately 2 km to the northwest. Much of the claim group is covered with overburden and is underlain primarily by conglomerates of the Coleman Member of the Gowganda Formation. These rocks overlie the upper contact of a Nipissing diabase sill.

The first phase of the program included extensive line-cutting, followed by a geological survey including surface outcrop sampling, soil and stream geochemistry, and a VLF survey. Anomalous areas were subsequently drilled with seven holes but no significant mineralization was encountered.

G.Q.R. Resources Limited hold a ten-claim property in Lorrain Township. The claims are underlain by upper contact Nipissing diabase and include a 200-foot deep shaft put down in the past on a known silver occurrence. Two holes were drilled to test the downward extension of this vein. The drillholes intersected a number of narrow carbonate veins carrying moderate amounts of chalcopyrite but no significant silver or arsenide mineralization.

Silver Century Explorations Limited acquired four claims in Coleman Township from Bursary Silver Mines Limited. Two weekend prospectors earlier discovered a new high grade occurrence of silver with a metal detector on this ground. The vein is exposed for a length of 15 m in upper contact Nipissing diabase. A sample from the outcrop revealed a 3 cm wide vein of etched white calcite carrying approximately 50% massive silver and very little arsenide material. The company has since brought in a drill and completed 12 shallow holes in the immediate vicinity of the find.

Phaeton Exploration Limited continued drilling an area including the eastern extension of veins previously mined for silver at the rich Cross Lake-O'Brien Mine in Coleman Township. Three deep drillholes were completed to test the Huronian sequence below the lower contact of a Nipissing diabase sill. A number of narrow carbonate and quartz veins were intersected but contained only minor magnetite and base metal sulphide minerals.

Stroud Resources Limited acquired the old Penrose Mine property in Strathy Township (Bennett 1978) early in the year and subsequently purchased an adjoining claim prospected last year by H. Neimetz (Owsiacki 1985a). The property hosts a number of well mineralized veins and shear zones characterized by the presence of erratic but good gold values. Lacana Mining Corporation has since entered into an option agreement which may eventually earn it a 70% interest in the property. During the Fall of 1985, this company carried out an extensive stripping and sampling program and plans follow-up drilling for the winter. Initial metallurgical tests of dump material have been completed.

Silverside Resources Incorporated maintained an active presence in the Cobalt area. The company optioned a group of claims from B. Ferguson earlier in the year in Lundy Township. The claims were staked on the basis of a silver/copper occurrence identified from recent mapping (Owsiacki 1985b). Eight diamond-drill holes were put down in the area, the second of which intersected a cobalt arsenide vein with significant silver values.

The claims are underlain by the basal portion of a Nipissing diabase sill which dips shallowly to the west. The intersected vein appears to be a downward extension of the surface occurrence and cuts thinly-laminated maroon argillites of the Firstbrook Member of the Gowganda Formation. Silver was identified visually within the core, 85 m below the sill. This may be the first known occurrence of silver within veins cutting this sedimentary horizon. Following this discovery, the company staked an additional 42 claims in the area.

Silver Lake Resources Incorporated, in conjunction with Silverside Resources Incorporated, continued exploration and development in the vicinity of an earlier silver discovery (Owsiacki 1984a) made in Lorrain Township. A decline was collared early in 1985 and advanced 665 m of a total proposed 823 m. Three drill stations have been cut and underground exploration drilling is currently in progress. Surface

exploration continued on this property with acquisition of a single claim in Bucke Township, adjacent to and north of the decline. In addition, a grid was cut over the southern limits of the property and followed with a VLF survey and 3353 m of diamond drilling.

Proteus Resources Incorporated hold a large group of claims adjacent to the south and east of the Silverside/Silver Lake ground in Lorrain Township. Drilling of 2229 m in eleven holes was completed in the vicinity of an old, previously recorded intersection.

Agnico-Eagle Mines Limited continued a surface exploration program around the Langis Mine in Harris Township. Surveys conducted in 1984 have subsequently been followed-up with a twelve-hole diamond-drill program. A few minor intersections were encountered and may be further investigated in the future. Additional line-cutting and VLF and magnetometer surveys were carried out in isolated parts of the property. The company also recently acquired an option on a five-claim group located adjacent to the Silverside Resources Incorporated discovery claims in Lorrain Township. A decline, previously put down by Teledyne Limited on these claims, has been pumped and an underground exploration drilling program is planned for the near future.

Canadaka Mining Corporation was established during the year and has an option to acquire all of Sulpetro Minerals Limited's area mines, mill, and properties. Underground workings have recently been de-watered and an exploration program, using the Conisil shaft for access is scheduled to begin by year-end.

K. Morgan acquired claims in Lundy Township and completed mapping and VLF surveys. Copper and minor silver and cobalt values were obtained from altered wallrock near intrusive Nipissing diabase dikes and plugs. Host rocks are primarily lower Lorrain Formation quartzites. These rocks have been baked red near the intrusions and contain disseminated and clotty chalcopyrite, azurite, malachite, and specular hematite (Owsiacki 1985b).

M. Shepherdson and R. Butler discovered a new cobalt showing in Dymond Township. Erythrite was observed coating a number of parallel fractures in Nipissing diabase. The men have since undertaken some overburden trenching and found it to be of little value because of the irregularity of the bedrock surface below a clay cover. The work has recently concentrated on exposing the fractures with trenching of the outcrop showings.

Exploration for gold in the Temagami greenstone belt increased markedly in 1985. Two companies, Inco Limited and Lacana Mining Corporation, executed extensive line-cutting programs on patented claims in the vicinity of Net Lake in Strathy Township. Geological and geophysical surveys were carried out and extensive stripping and trenching undertaken on the Lacana ground. Drill programs have been proposed to start in the near future in this area.

Numerous other companies were active in the area and include Temco Mines Limited, Kyanite Mining Corporation, Pronto Explorations Limited, Nortario Limestone Limited, Bigstone Minerals Limited, Danra Resources Limited, Teck Corporation, Outcrop Explorations Limited, Hudson Bay Mining and Smelting Company Limited, Stroud Resources Limited, BP Canada Incorporated, Exploration Aiguebelle Incorporated, Profenix Enterprises Limited, Golden Associates, Falconbridge Limited, Addson Resources Limited, Temrex, Knox-Martin-Kretch Limited, Sulpetro Minerals Limited, and Boston Creek Mines Limited.

Prospecting activity remained at a fairly high level despite the negative effects of a Land Caution filed in the past by the Temagami Indian Band. A more complete summary of exploration activity in the Cobalt Resident Geologist Area in 1985 is provided in Table 8.2 and Figures 8.1a and 8.1b.

Data submitted for assessment purposes or donated are summarized in Table 8.3 and relevant Ontario Geological Survey and Geological Survey of Canada publications are listed in Table 8.1.

INDUSTRIAL MINERALS

LIMESTONE/DOLOSTONE

In the past two years, there has been a dramatic rise in both development and exploration for limestone and dolostone in this area. Much of the recent interest can be attributed to the decision by Dofasco Incorporated to develop an on-site iron flux pelletizing process at the Sherman and Adams Mines. This pelletizing process is designed to use a flux composed of a limestone-dolostone blend which, at present, is shipped by rail from Southern Ontario. In order to make the process more economical, a local source of flux is desirable.

It has become apparent that the Paleozoic outlier in this region hosts a variety of potentially exploitable rock types ranging from low silica, high magnesia dolostone to low silica, high calcium limestone. Many companies, including Dymond Clay Products Limited, Nortario Limestone Limited, Exploration Aiguebelle Incorporated, and Sherman Mine, have expressed interest in locating and developing properties in the area. At present, several of these companies are operating quarries within the Paleozoic Outlier. Dymond Clay Products Limited quarries high calcium, low silica limestone for metallurgical and agricultural markets. Nortario Limestone Limited operates a quarry near Earlton and produces crushed stone for aggregate, in addition to high magnesia, low silica dolostone used in metallurgical processes. Two other minor quarries are located in the Outlier but operate only intermittently. One produces flagstone and the other is operated by the Township of Harley to provide rock fill for township projects. A quarry operated by Exploration Aiguebelle Incorporated in Quebec, located on the eastern shore of Lake Temiskaming, produces dolostone for agricultural uses. Increased demand for these products in an expanding local market and the recent successes of local operators will undoubtedly result in further exploration and development in the coming years.

Dymond Clay Products Limited remains the only limestone producer within the Cobalt Resident Geologist's area. Shipment of their product during the Spring of 1985 was restricted because of a lack of drying facilities. To meet this requirement, a large

storage shed, capable of housing 6000 tonnes of crushed material, was completed in July. Regular shipments of metallurgical limestone to Kidd Creek Mines Limited started in June and will now continue year-round with daily deliveries. The pit was extended in November to the north and new material crushed for winter storage. Production of the more valuable metallurgical limestone increased in 1985 to approximately 6000 tonnes from 1780 tonnes in 1984. Seventy percent of this material was shipped to the Kidd Creek Mines smelter in Timmins and 30% to the Noranda Mines smelter in Noranda. Agricultural limestone shipments increased to 2000 tonnes from 241 tonnes and limestone aggregate to 2500 tonnes from 703 tonnes. Full production should be reached in 1986.

BUILDING STONE

Quarrying of decorative building stone was carried out in three townships in the North Bay area. The largest producing quarry is located on Reynolds Lake in McAuslan Township. Approximately 258 tonnes of two major types of stone were removed by the operator, McClaren's Bay Mica Stone Quarries. The stone is comprised of both red and green micaceous quartzose gneisses, cut by abundant quartz veining. Two minor and intermittent producing quarries are located in Poitras Township and a third in Jocko Township.

ONTARIO GEOLOGICAL SURVEY ACTIVITIES

GEOPHYSICS/GEOCHEMISTRY SECTION

A geophysical study of the Cobalt Embayment was initiated in 1980. Some results from this work remain to be interpreted (Gupta 1985).

RESEARCH BY OTHER ORGANIZATIONS

CARLETON UNIVERSITY

G. Burbidge continued regional field studies investigating the sedimentology of the Gowganda Formation as part of a Ph.D. thesis. The Coleman Member, in particular, was studied in the Temagami area this past summer.

M. Smyk began research, as part of an M.Sc. thesis, on the sulphide mineralogy of Archean interflow sediments and its relationship to silver-bearing carbonate veins in Cobalt.

P. McRobbie is completing detailed mapping of a small area of the Archean basement on Nipissing hill in Cobalt as part of a B.Sc. thesis project.

UNIVERSITY OF TORONTO

D. Conrod continued field investigations of Nipissing diabase in the Cobalt area as part of an M.Sc. thesis. Petrology, geochemistry, and isotopic studies of these and similar intrusions near Sudbury are being compared and platinum group element potential established.

McMASTER UNIVERSITY

R.J. Bowins carried out analytical determinations of rare earth element contents in the Sherman and Adams Mines iron formation deposits (Crocket and Bowins 1985) as part of a Ph.D. thesis.

[4]District Geologist, Ontario Ministry of Northern Affairs and Mines, Wawa

[5]Contract Geologist, Ontario Ministry of Northern Development and Mines, Sault Ste. Marie

INTRODUCTION

The permanent staff of the Sault Ste. Marie Resident Geologist's office consists of E.J. Leahy, Resource Geologist and G. Bennett, Resident Geologist. Brenda Fremlin continued on contract as secretary. The Drill Core Library program continued under the immediate direction of J.P. Donald. A report of the activities of the Drill Core Library staff is included in this report. E.D. Frey assumed the duties of District Geologist for the Wawa District on April 1, 1985.

A study of magnetic and geochemical anomalies and greenstone enclaves in the granitic terrain between the Montreal River and the Michipicoten metavolcanic-metasedimentary belt was continued under the direction of D.J.J. Tortosa with the assistance of E.J. Haley.

The Wawa Economic Geologist Program continued in 1985. As the second phase of the program, T. Howson, J. Melisek and W. Wing were employed on contract to compile Geological Data Inventory Folios (GDIF) of the Wawa-Goudreau area. The Sault Ste. Marie Industrial Minerals Program continued under the supervision of J.J. Kral, assisted by P. Beach during the field season.

The preceding three projects were originally funded by the Ministry of Northern Affairs (now the Ministry of Northern Development and Mines). The preliminary results for these projects are included in this report.

L. Ashick and D. Messenger were employed on a contract Fo compile Geological Data Inventory Folios of the Sault Ste. Marie and Batchawana areas. This work is funded by SPARC (Special Projects to Assist Resource Communities).

A pilot project to enter GDIF data into a local, stand-alone computerized database was undertaken in 1985. Entry programs were written by J.P. Donald and data was entered by D. Genys. As of December 1985, the following GDIFs have been completed and should be published by Spring, 1986: Anderson Township, Bruyere Township, Corbiere Township, Copenace Township, Daumont Township, Dolson Township, Dumas Township, Dunphy Township, Echum Township, Gaudry Township, Glasgow Township, Hughes Township, Loach Township, Lunkie Township, Raaflaub Township, Riggs Township, Running Township, Tupper Township, West Township, and Wishart Township.

In October of 1985, M.J. Cook, assisted by S.F. Uhler, carried out a reconnaissance survey of known tailings areas and "ore" piles of past gold producers in the Wawa-Goudreau area.

J. Lucuik assisted with computer data entry under the Experience '85 program during July and August.

RESIDENT GEOLOGIST ACTIVITIES

The number of public inquiries to the Sault Ste. Marie Resident Geologist's office in 1985 was down only a little from the record years of 1983 and 1984. As a result, much of the Resident Geologist's time was spent responding to requests for information and consultation. In addition, talks on general geological subjects and the results of exploration in the Hemlo area were given to a local high school. A geological field trip through the Thessalon area was conducted for an industry group. A few days were spent on a reconnaissance of the geology of Michipicoten Island. The Resident Geologist assisted John A.C. Fortescue, Ontario Geological Survey, with a remote sensing evaluation in the Montreal River area in August. The Resident Geologist visited twelve active and nine inactive properties during the 1984 field season. Research was continued on a study of the lower Huronian stratigraphy and Huronian volcanic rocks between Elliot Lake and Sault Ste. Marie. Most of the Resident Geologist's time was spent in administrative duties pertaining to two permanent and four temporary projects.

During the past year, the Resource Geologist gave presentations at two local schools; supervised the preparation of Geological Data Inventory Folios; supervised an industrial minerals project carried out by J. Kral, and prepared six sets of rocks and minerals for the Sault Ste. Marie School Board. A detailed literature search and field investigations were carried out by the Resource Geologist with reference to the Bruce Mines hazard lands. He also carried out ongoing revisions to the microfiche assessment file library; indexed and added to the technical articles file. The Resource Geologist spent a great deal of time assisting visitors to the Sault Ste. Marie office and responding to inquiries from local prospectors, industry, and the public.

WAWA DISTRICT GEOLOGIST ACTIVITIES

The office of the Wawa District Geologist has been in service since January 2, 1985. Permanent staff consists of E.D. Frey, District Geologist. Temporary field and office assistance was provided in October and November by S.F. Uhler. Administrative and logistical

support is provided by the Wawa District of the Ministry of Natural Resources (MNR).

The area served by the District Geologist is the northern half of the Sault Ste. Marie Mining Division. It corresponds to the Wawa District of the Ministry of Natural Resources, with the omission of Leeson, Baltic, and Kildare Townships (Figure 9.1).

Office facilities include an updated reference library of Ontario and federal government geological maps and reports on the geology of the Wawa district, a microfiche file of mining claim assessment work reports for the district, and a microfiche reader-printer. In addition, mining claim maps, tags, and prospector licenses are sold by the MNR Land Management Branch.

Operation funding has been provided partially by the Wawa Economic Geologist program of the former Ministry of Northern Affairs (now the Ministry of Northern Development and Mines) and the Mineral Deposits Section of the Ontario Geological Survey (OGS).

The primary activities of the Wawa District Geologist consist of providing information services and technical advice to prospectors and geologists from the exploration, academic, and government communities, and to the general public. Much of this work was in the form of conducting 31 organized and impromptu field trips to examine Wawa area geological features and (mainly) gold occurrences.

Sampling and preliminary mapping of twenty new occurrences and dormant and developing prospects provided additional assistance to prospectors, and information for future new and updated Geological Data Inventory Folios. The District Geologist also visited six major active exploration projects.

Other field activities included presenting introductory geological lectures and field trips to three MNR Junior Ranger camps; brief geological reconnaissances of the southern and western shore of Michipicoten Island and the Hawk Lake-Manitowok Lake contact zone of the Wawa metavolcanic-metasedimentary belt and "external" granitic terrain; a preliminary appraisal of the mappability of strain indicators in the Wawa area; and continued reconnaissance scale Quaternary mapping of the Hawk Junction NTS map sheet. Office and telephone consultations totaled 451 for the first 11 months of the year. Direct service to Wawa MNR District included editing geological introductions for several forest management plans and participating on the District Roads Committee.

External conferences and field trips attended included: the Institute on Lake Superior Geology in Kenora, the Canadian Institute of Mining and Metallurgy Granite-Related Mineral Deposits Conference in Halifax, the OGS Hemlo-Geraldton field trip, and the OGS Building Stone Seminar in Kingston-Cornwall.

TAILINGS INVENTORY

A tailings inventory survey of past-producing gold mines in the Wawa-Goudreau areas was inititated in October 1985. The field work was supervised by the Wawa District geologist and carried out by M.J. Cook assisted by S.J. Uhler. The known tailings disposal areas and "ore" dumps of sixteen past producers were surveyed using simple chain and compass methods. The calculated volumes and tonnages of materials surveyed and location maps will be released as an open file report. A limited number of samples were collected for analysis by the Geoscience Laboratories of the Ontario Geological Survey.

CURRENT RESEARCH IN THE WAWA AREA

V. Coleman of Carleton University is conducting a study of the deformation of variolites in the Wawa-Goudreau area as part of the requirement for a B.Sc. degree in geology.

T.M. White is preparing a B.Sc. dissertation at the University of Western Ontario on the subject of glacial till genesis in the White River area.

R.G. Reid, presently at the University of Windsor, is studying the volcanic stratigraphy and geochemistry in the Mishibishu Lake area.

K. Thomson is continuing a study of the clastic and chemical metasediments of part of the Hemlo area, including White Lake Provincial Park.

G. E. McGill, of the faculty of the University of Massachusetts, is conducting structural studies in Chabanel Township.

C. Chrady, a Ph.D. candidate at the University of Massachusetts, is conducting structural studies in Chabanel Township.

CLAIM STAKING ACTIVITY

Between January 1 and November 30, 1985, 1603 mining claims were recorded in the Sault Ste. Marie Mining Division. This compares to 1555 mining claims staked during the same period in 1984.

MINING ACTIVITY

The Algoma Ore Division of the Algoma Steel Corporation Limited continued to mine siderite iron ore at the George W. MacLeod Mine in Wawa during 1985, except during a 5-week shutdown between late July and early September. Production for 1985 through the end of November was 1.24 million long tons of iron sinter from 1.8 million long tons of ore.

Denison Mines Limited continued production of uranium oxide from its mine and mill at Elliot Lake.

Rio Algom Limited continued operation of the New Quirke, Stanleigh and Panel Mines in the Elliot Lake area. Uranium oxide production for the first nine months of 1985 was reported to be slighly lower than the comparable period for 1984. Rio Algom is proceeding with the construction of a 150 ton per day yttrium plant which is scheduled for completion in 1987.

In the fall of 1985, Sill Lake Silver Mine Limited resumed mining and milling operations at the former Prace Mine in Vankoughnet Township. The essential elements of the recently constructed 120 ton per day mill include a ball mill, two Rikker spirals, and 10 flotation cells. Eighteen men are employed at the Sill Lake facility. Eighty tons of lead-silver concentrates were shipped in 1985.

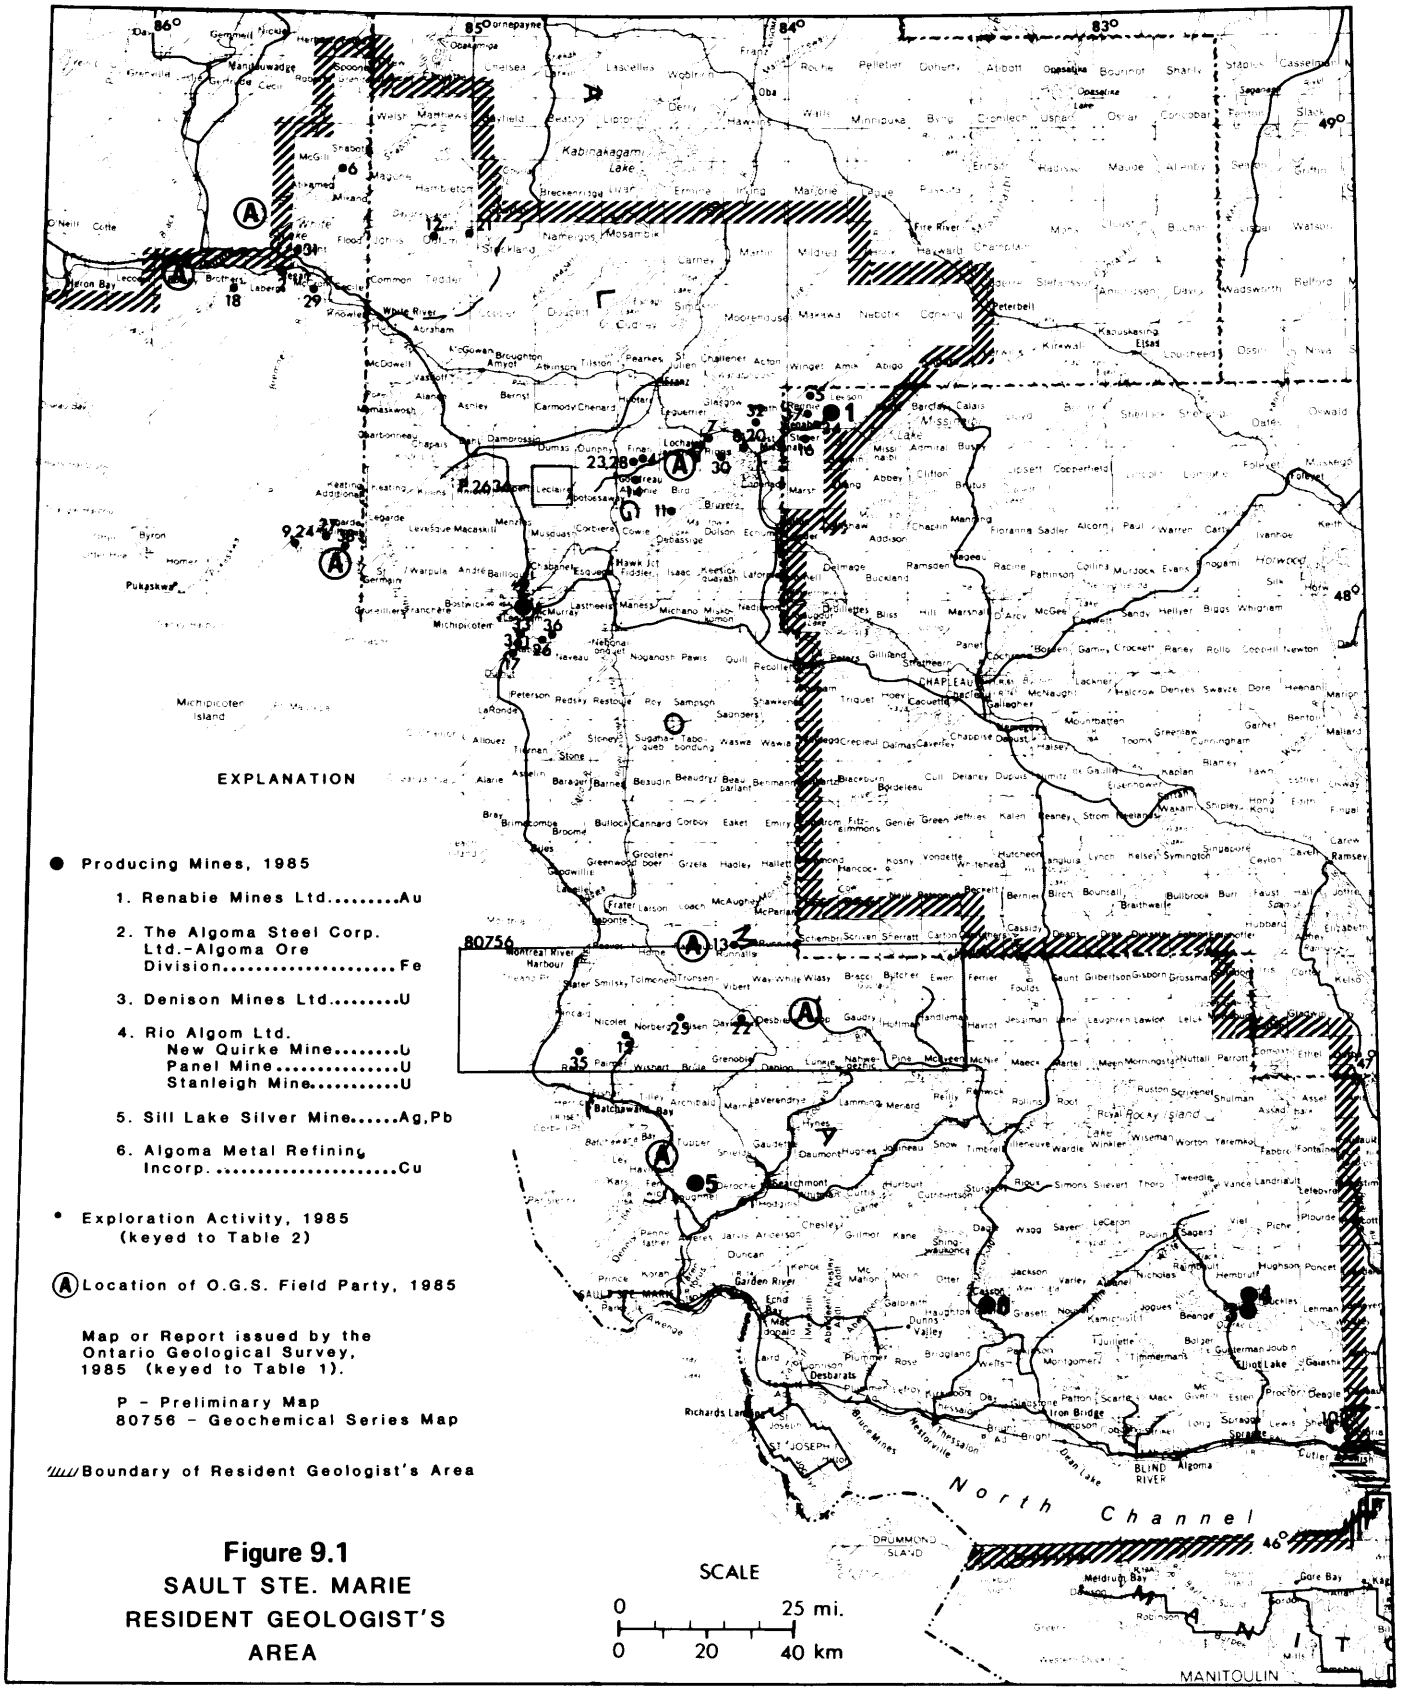

Figure 9.1
SAULT STE. MARIE RESIDENT GEOLOGIST'S AREA

Algoma Metal Refining Incorporated shipped 200 tons of copper concentrate to Kidd Creek Mines Limited from its adit and mill in Gould Township. About 30 tons of this concentrate originated as "flux ore" from the Dolbreck Mines Limited property in Parkinson Township. The capacity of the 125 ton per day mill on the property is currently being increased.

Sill Lake Silver Mine Limited, Algoma Metal Refining Incorporated, and Dolbreck Mines Limited are operated by Elsadon Explorations Limited, a privately owned corporation.

EXPLORATION ACTIVITY

Mineral exploration activity in the Sault Ste. Marie Mining Division in 1985 continued at a relatively high, but slightly reduced level, from that of the previous years. Again, gold was the commodity of choice. Base-metal prospects rarely received attention unless there were known associated precious metals.

Table 9.1 summarizes the exploration activity in the Sault Ste. Marie Mining Division during 1985.

GOLD

Gold exploration, fueled in several cases by successful "flow-through" financing, led an increasing pace of exploration through the year in the district. Table 9.1 and Figure 9.1 provide a summary of exploration activity in Wawa District during 1985. The major activities, highlighted below, were reported by personal communication with company representatives.

Canamax Resources Incorporated commenced underground exploration of its Kremzar Gold Prospect in Finan Township in November with a spiral ramp to facilitate bulk sampling. An extensive surface drilling program has continued throughout the year, indicating reserves of 870 000 tons of ore at a grade of 0.23 ounce gold per ton. The property is a 50-50 joint venture with Kremzar Gold Mines Limited (79% controlled by Algoma Steel Corporation Limited).

In the Goudreau area, Muscocho Explorations Limited has completed 29 drillholes for a total length of 16 100 feet (4900 m), mostly on the western zone of the former Algoma Summit Gold Mines (Magino) Property. The project is a joint venture with McNellen Resources Incorporated. Further drilling is planned for 1986.

In the Mishibishu Lake area, Muscocho Explorations Limited completed 98 drillholes totaling 46 000 feet (14 000 m) on its gold prospect, shared with Flanagan McAdam Resources Incorporated (50%) and Windarra Minerals Limited (25%). Westfield Minerals Limited completed 9 drillholes for a total of 1890 feet (575 m) on the "Discovery" gold showing of its portion of the same mineralized zone, southeast of the Muscocho Prospect. Both companies plan to continue exploration in 1986.

In Rennie Township, Canamax Resources Incorporated completed nine drillholes on its Conboy Lake zinc-silver-gold joint venture prospect with Westfield Minerals Limited.

Monk Gold Mines Limited began extensive exploration of its Naveau and Rabazo Townships gold prospect in November. Ground geophysical surveys and over 15 000 feet (4500 m) of diamond drilling have been contracted for the remainder of 1985. In addition, the company has begun underground exploration through the expansion of an existing shallow decline. Further work is planned for 1986.

Sault Meadows Energy Corporation and First Canadian Energy Corporation Incorporated completed a mapping, trenching, and 2500-foot (750 m) drilling program on their joint venture gold prospect on the Centennial Mine Property in Naveau Township. Exploration will continue in 1986.

Golden Vale Explorations Corporation completed 2 drillholes of 600 feet (180 m) each on its Debassige Township gold prospect. No further work is planned at the present time.

Massive Energy Limited holds 263 claims by staking and an additional 32 claims by option arrangements in the Batchawana-Pangis area about 70 km north of Sault Ste. Marie. The property includes parts of Davieaux, Desbiens, Tronsen, and Olsen Townships. During the winter of 1985, Massive Energy completed a 5000-foot drilling program of 29 holes in Davieaux Township. In March of 1985, the company reported that hole No. 10, collared about 40 m east of the trench on the previously known gold occurrence of New Hiawatha Mines Limited, intersected 67.5 feet (core length) of 0.103 ounce gold per ton, including a 16.4-foot section of 0.246 ounce gold per ton. Hole No. 9 (from the same setup) intersected 46.3 feet of 0.069 ounce gold per ton, including 16 feet of 0.105 ounce gold per ton. The mineralized zone is at the bedrock surface. The company geologist describes the mineralized unit as "iron formation" and part of the geochemically anomalous (in gold) chert-pyrite unit which has been the focus of much, but by no means all, of Massive Energy's exploration effort in the Batchawana area. The company recently announced that it has secured financing to carry out a definition drilling program on the mineralized zone.

Sands Minerals Corporation holds 203 claims in Vibert Township in the Batchawana area immediately north of the Massive Energy property referred to in the preceding paragraph. A ground Max-Min electromagnetic survey, a magnetometer survey, and a soil geochemical survey were carried out in 1985.

Master Resources and Development Limited acquired an option to earn up to 50% interest in the 35 claim group of Dejour Mines Limited in Davieaux Township. This property is immediately south of the Massive Energy Property. In 1985, Master Resources completed soil geochemical surveys begun by Dejour Mines Limited and carried out reconnaissance and detailed geological surveys over the claim group.

Jonpol Explorations Limited purchased 135 claims in Norberg and Nicolet Townships of the Batchawana area in 1984. These claims include the former Tribag Mine, a past producer of copper and silver. In 1985, Jonpol carried out low level airborne magnetic surveys followed by a diamond drilling program as part of a search for additional copper-precious metal bearing breccia pipes of the Tribag type.

EXPLORATION ACTIVITY DURING THE YEAR.

TABLE 9.1

Number on Figure	Individual or Company	Activity
1.	Algoma Silver-Lead Limited	Drilling, Deroche Township

SAULT STE. MARIE DRILL CORE STORAGE LIBRARY

For 1985, staff in the Sault Ste. Marie Core Storage Library included J. Melisek, D. Messenger, and M. Goudreau as geological assistants; R. Sanderson and P. MacEachern as summer assistants; and J. Donald as library geologist.

A total of 10 500 m of drill core was collected from 17 sites, representing 17 400 m of drilling. As of December 1985, the facility contained 53 000 m of core representing 175 000 m of drilling.

Most drill core was recovered by truck; however, 17% was transported by helicopter (to a trucking point), 23% by float plane, and 5% by boat. The remote core locations and difficult means of access necessitated the use of alternate transportation, thereby reducing the total amount of core retrieved in comparison to previous years.

In addition to drill core, the Core Library contains several thousand rock samples and hundreds of petrographic thin sections. Information regarding these items is stored in computer files for retrieval by staff at the clients' requests.

A biannually updated catalogue of the drill core inventory is available free upon request; clients can be added to an automatic mailing list at no charge by contacting the Sault Ste. Marie Resident Geologist's office.

ALGOMA RECONNAISSANCE GEOLOGY PROJECT

INTRODUCTION

The Algoma Reconnaissance Geology Project continued into its second year, concentrating on the granitic and gneissic terrains between the Michipicoten and Batchawana metavolcanic-metasedimentary belts (Figure 9.2, Area 2). The project was initiated in order to evaluate the source and nature of selected geological, geochemical, and geophysical anomalies within the granitic and gneissic terrains of the Algoma Region, and to determine whether they represented targets of possible economic interest for follow-up by the mining and exploration community.

Targets to be evaluated were based on aeromagnetic, geochemical, and geological anomalies defined by previous federal and provincial surveys. The reconnaissance study focused on the Kinniwabi Lake, and the Millwood areas (Figure 9.3), since these contained several metavolcanic-metasedimentary enclaves, geochemical, and geophysical anomalies, and were easily accessible by a well developed timber road system. Other geological and geophysical targets and mineral occurrences were accessed by helicopter, fixed-wing aircraft, boat, and all-terrain vehicles. Summer field work was based out of Wawa and started in mid-June under the supervision of D. Tortosa assisted by E. Haley.

GEOLOGICAL SETTING

The granitic and gneissic terrains throughout Area 2 (Figure 9.2) are shown on the geological compilation map, Map 2220 (Milne *et al.* 1972), as consisting of granitic, granodioritic, dioritic, and trondhjemitic gneisses and massive granitic rocks containing small isolated metavolcanic-metasedimentary enclaves. The rocks are transected by north-, east-, and northeast-trending lineaments, and by north-, northwest-, and northeast-trending diabase dikes. Card (1979) in a regional geological synthesis of the *Central Superior Province* shows the area as belonging to the Anjigami Gneiss Domain which consists predominantly of tonalitic and granodioritic gneisses intruded by felsic plutonic rocks and containing metavolcanic-metasedimentary enclaves interconnected by zones of migmatite.

The area under investigation is contained within a part of the Superior Province which has been interpreted by Percival and Card (1985) as representing an oblique cross section through a 20 km thick slab of Archean crust that was differentially uplifted along a major northwest-dipping thrust (the Ivanhoe Lake Cataclastic Zone). They base this interpretation, in part, on a continuous transition in erosional levels extending from the Michipicoten metavolcanic-metasedimentary belt (low grade, upper crust), through tonalite gneiss and felsic plutonic terrain (medium to high grade, mid crust), into heterogeneous high grade gneisses of the Kapuskasing Zone (deep crust).

The study area forms part of what Percival and Card (1985) refer to as the mid crust "megalayer" consisting of a tonalitic gneiss complex with large-scale domal structures and felsic intrusions. The gneissic complex contains large xenoliths of metavolcanic-metasedimentary rock, up to several kilometres long, which become more common near the margins of the Michipicoten metavolcanic-metasedimentary belt. U-Pb dates of zircons in the tonalitic gneisses (Percival and Card 1985) indicate that they were emplaced during the late stages of volcanism in the Michipicoten belt (2749 to 2696 Ma); this leads Percival and Card to suggest that the metavolcanic-metasedimentary enclaves were formed by the stoping the margins of the supracrustal pile.

FIELD INVESTIGATIONS

Metavolcanic-metasedimentary enclaves up to several kilometres long are contained within tonalitic to granodioritic gneiss and are interconnected and partly enveloped by zones of migmatite. The enclaves are composed predominantly of amphibolite and amphibole-feldspar gneiss; however, some enclaves contain sections of felsic to intermediate metasediments and metavolcanics (2G-3 and 2G-5, Figure 9.2). Three areas previously thought to be underlain by metavolcanics or metasediments (2G-2, 2G-6, and 2G-7, Figure 9.2) were not confirmed during ground follow-up. Area 2G-2 is underlain by tonalitic gneiss, migmatite, and gabbro intrusions; 2G-6 consists of quartzo-feldspathic paragneisses; and 2G-7 consists of quartzo-feldspathic paragneiss with a variable mafic mineral content. Two large metavolcanic-metasedimentary enclaves in the Kinniwabi Lake and Jackpine River area, 2G-1 and 2G-8 respectively (Figure 9.3), are covered by a blanket of glaciofluvial debris resulting in very poor outcrop exposure. The Kinniwabi Lake metavolcanic-metasedimentary segment is unique in that rock foliations are shallow dipping to nearly flat lying, and the immediately enclosing gneissic and migmatitic rocks display a shallow-dipping gneissosity.

Many northwest-trending linear aeromagnetic anomalies in the area coincide with the position of similar trending diabase dikes. Where dikes are exposed on surface, and particularly at rock cuts on Highway 101, they exhibit sharp contacts with the granitic and gneissic country rocks. There is little evidence of post-intrusion fracturing and shearing at the contacts, as commonly occurs in mafic dikes north of Sault Ste. Marie (Area 1, Figure 9.2). The northwest-trending dikes in the Wawa area have been correlated with the Matachewan swarm (Rb-Sr 2633 Ma; Gates and Hurley 1973) and the Sudbury swarm (ca. 1250 Ma; Van Schmus 1975). Several irregular aeromagnetic anomalies visited were either caused by mafic or tonalitic gneiss containing Fe-Ti oxides (2M-1 and 2M-3), or by magnetite-bearing cherty ironstone (2M-2, Figure 9.3).

Uranium geochemical anomalies in lake sediment and water (OGS-GSC 1979) were investigated in order to determine their source. Traverses over geochemical anomaly 2SSM-1 (Figure 9.2) indicate that the underlying rock is granite, intruded by radioactive pegmatites containing a black radioactive mineral (possibly uraninite). Background radioactivity (total count) over the granite is 2 to 3 times more than the surrounding tonalitic gneiss and migmatite terrain.

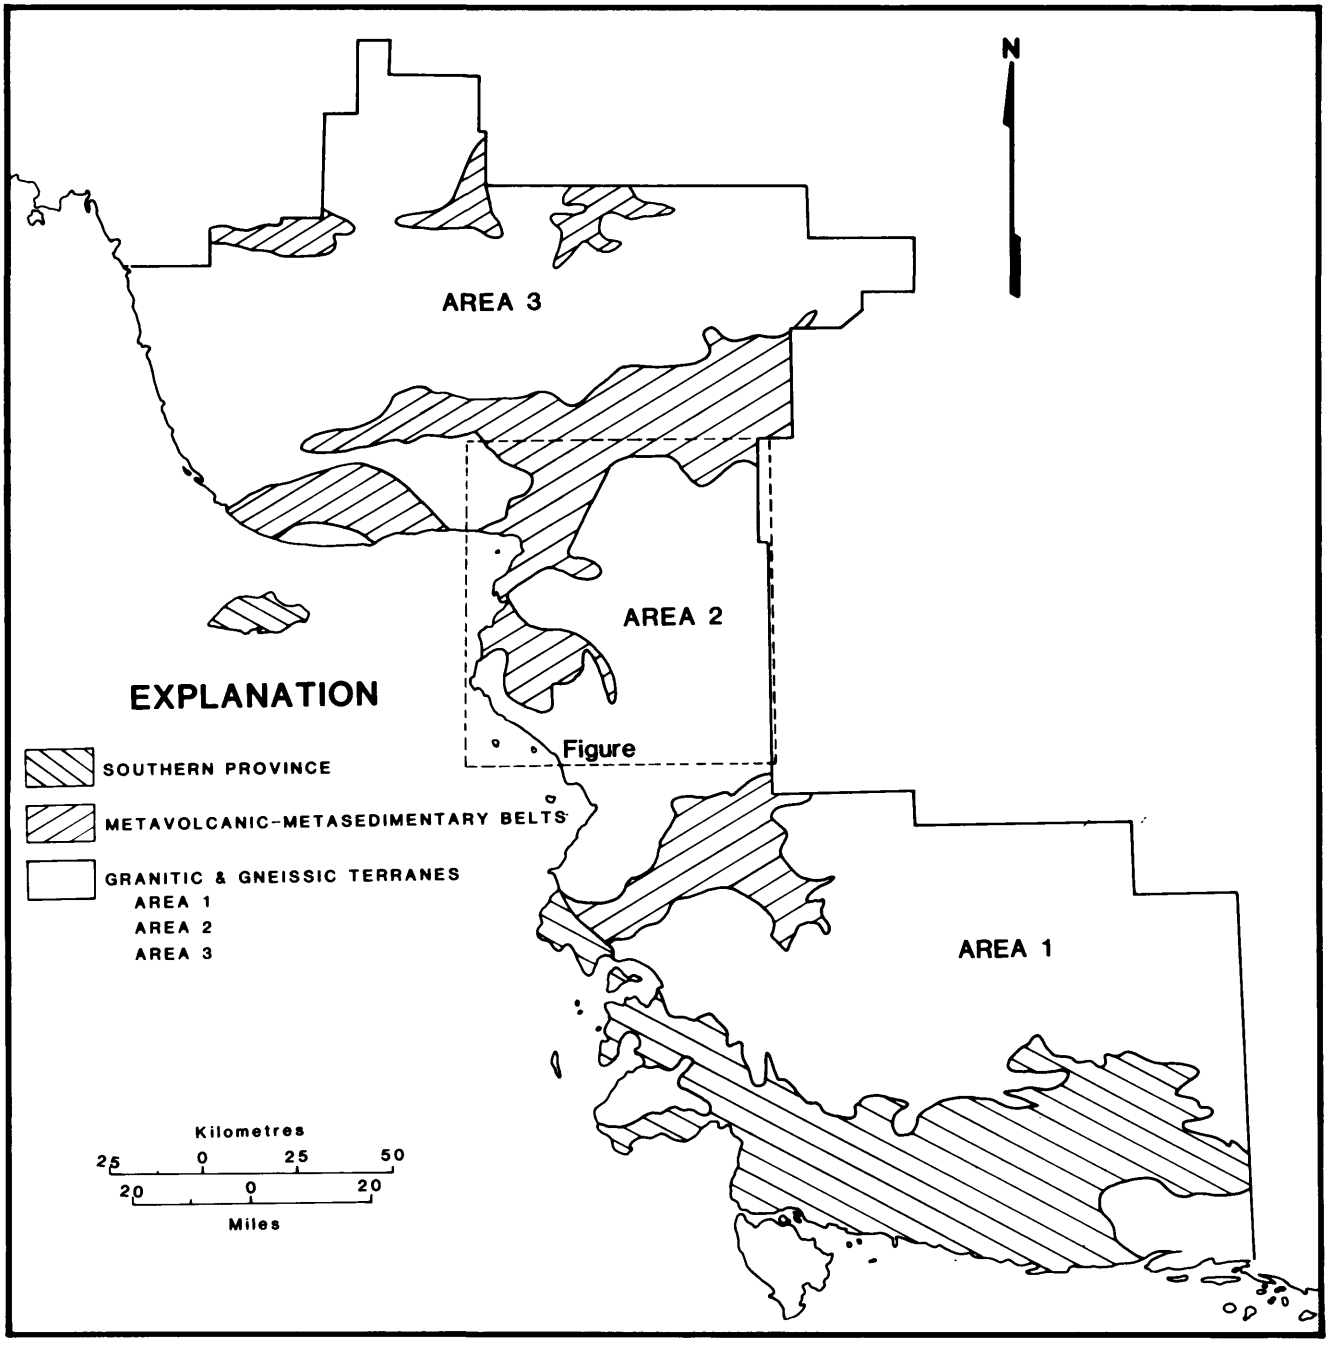

Figure 9.2 . Algoma Reconnaissance Geology Project

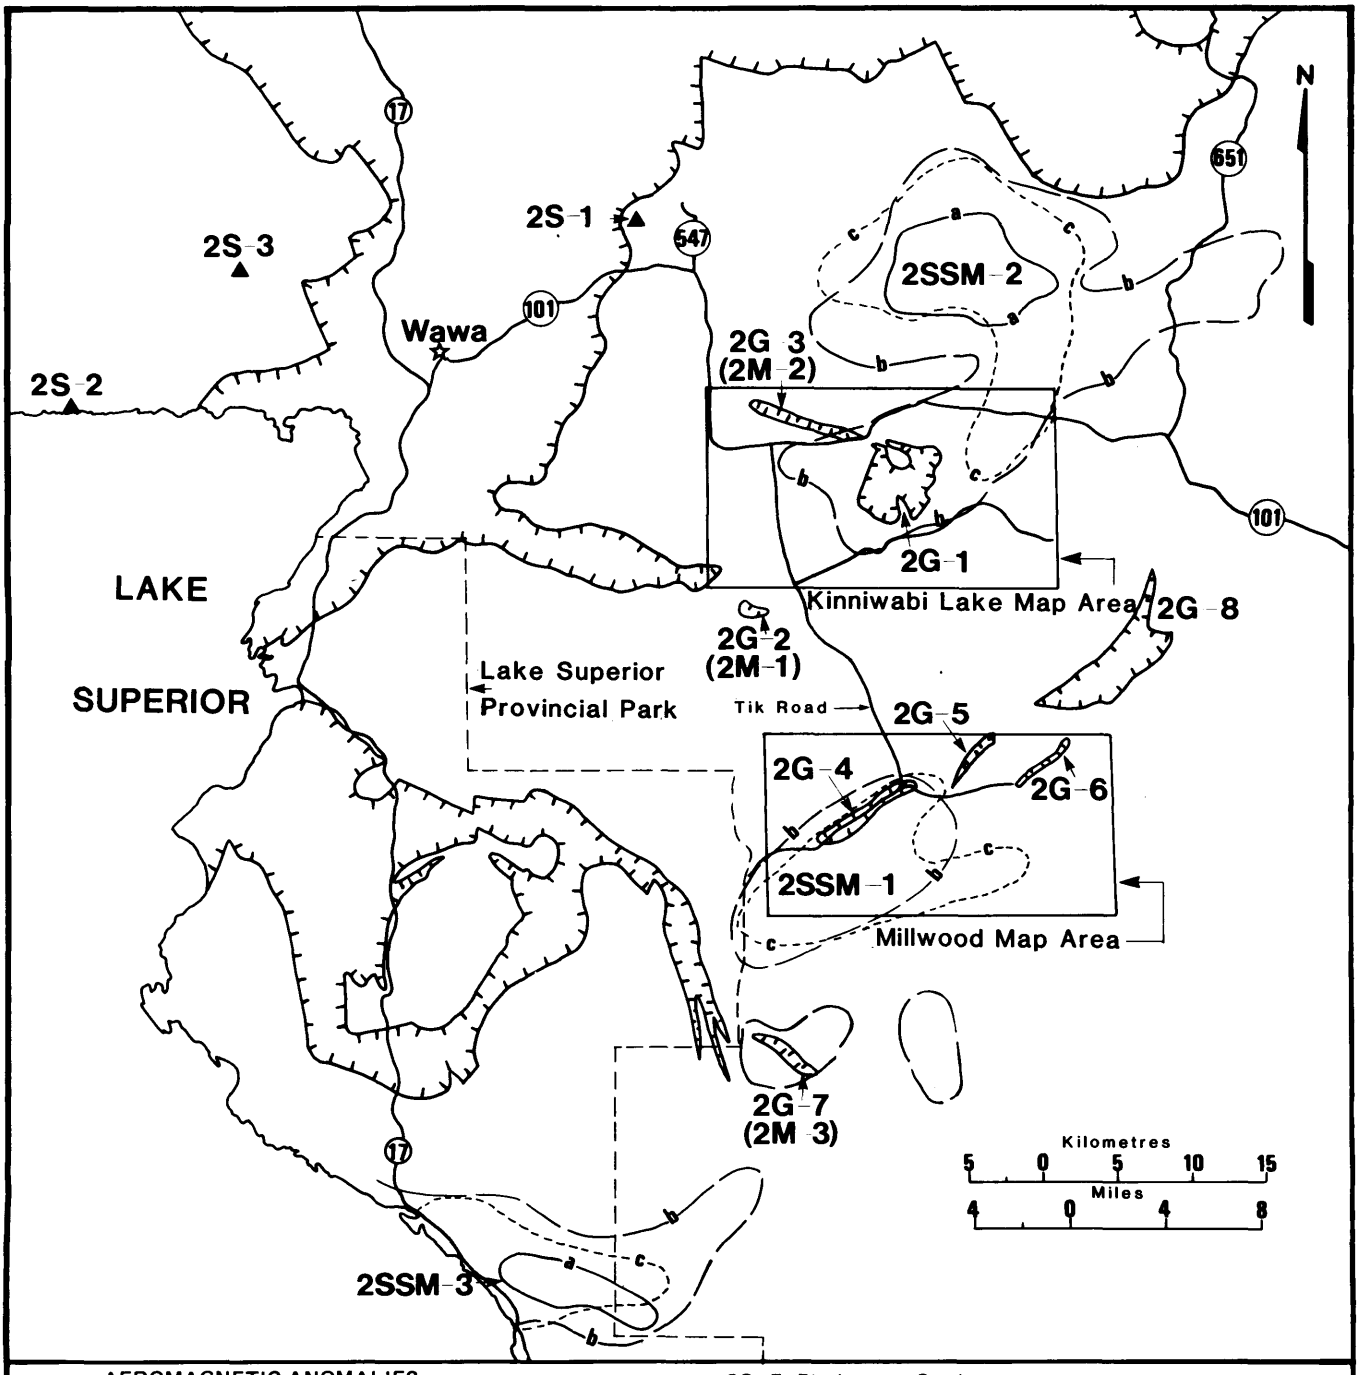

AEROMAGNETIC ANOMALIES

2M–1: Powerline Road Aeromagnetic anomaly (Tonolite Gneiss)
2M–2: Michipicoten Dam Aeromagnetic anomaly (Cherty Ironstone)
2M–3: Blackspruce Creek Aeromagnetic anomaly (Mafic Gneiss)

GEOLOGICAL TARGETS

Kinniwabi Lake Map Area
2G–1: Kinniwabi Lake
2G–2: Powerline Road
2G–3: Whitefish-Shikwamkwa Lake

Millwood Map Area
2G–4: Agawa River
2G–5: Mount Baldy
2G–6: Berry Lake
2G–7: Blackspruce Creek
2G–8: Jackpine River

MINERAL OCCURRENCES

2S–1: Regenery Metals Molybdenite Occurrence
2S–2: Crane Tungsten Occurrence
2S–3: Ranwick Molybdenite Occurrence

REGIONAL GEOCHEMICAL ANOMALIES (Uranium)

2SSM–1, 2SSM–2, 2SSM–3

Lake Sediments a: 20 ppm U
b: 7.6 20 ppm U

Lake Waters c: 0.16 ppb U

NOTE: Hatchured boundaries represent the outlines of metavolcanic-metasedimentary belts or enclaves.

Figure 9.3 . Aeromagnetic anomalies examined in 1985

Geochemical anomaly 2SSM-2 overlies massive felsic plutonic rocks ranging from granite to granodiorite in composition and containing minor tonalite gneiss and migmatite. The size and shape of the anomaly tends to correlate roughly with the surface extent of the plutonic mass. Elevated uranium levels for geochemical anomaly 2SSM-3 (Figure 9.3) can be attributed, in part, to the presence of pitchblende occurrences in the immediate area. It would appear that the elevated concentration of uranium in lake sediments and waters in these anomalies is mostly derived from the surrounding uraniferous pegmatites and granites and, locally, from pitchblende occurrences of the Montreal River area. Friske (1985), in an interpretation of the geochemical data from the north shore of Lake Superior, shows that these anomalies are contained within a much broader and larger area of elevated uranium in lake sediments and waters, which is underlain by granitic and gneissic terrain. He attributes these regional trends to the above average uranium content in the underlying granitoid terrains, and to pitchblende mineralization in the Montreal River area.

The few mineral occurrences within the study area consist of either Mo (2S-1 and 2S-3, Figure 9.3) or Mo-W (2S-2) occurring in quartz veins transecting mostly granitic and gneissic country rocks. The Regnery Metals Molybdenite Occurrence (2S-1, Figure 9.3) consists of northeast-trending, southeast dipping quartz-sulphide veins up to 1 m wide and 30 m long which are closely associated with, and occur between, similar trending, coalescing diabase dikes intruding granite and quartz porphyry (Assessment File Esquega 0019, Sault Ste. Marie Resident Geologist's Office). A quartz-sulphide vein exposed on the surface consists of a 5 to 15 cm thick chalcopyrite-pyrite vein contained within an envelope, up to a metre wide, of silicified granite or quartz porphyry. Molybdenite occurs as disseminated flakes within quartz and at the contact between the sulphide vein and the quartz.

The occurrence was originally developed by Regnery Metals in the late 1930s for its molybdenum and (supposed) beryllium potential, utilizing an inclined shaft and workings at inclined depths of 90 and 230 feet (28 and 70 m). In 1958, International Ranwick Limited dewatered the shaft, resampled the underground workings, completed a drill program on the second level, and outlined 13 000 tons of ore at 0.11% Mo based on a 1.16 m mining width. Grab samples taken of vein material by the authors gave assays of 13% Cu, 2700 ppb Au, and 950 ppm Ni. Approximately 1 km east of the occurrence, along the access bush road, a quartz-sulphide vein was found contained within a northeast-trending diabase dike which assayed 2.9% Cu, and 110 ppb Au. (Analyses by the Geoscience Laboratories Ontario Geological Survey, Toronto.)

The Ranwick Molybdenite Occurrence consists of three main sets of quartz-filled gash fractures in quartzo-feldspathic gneisses and granodiorite. The quartz veins trend north-northeast, east-northeast, and south-southeast, dipping vertically, and ranging from 5 cm to 3 m wide and between 1 and 20 m long. Molybdenite occurs as 1 to 2 cm flakes and clusters of flakes in quartz near the vein contacts, and within a 10 cm envelope in the adjacent country rock. The mineralization tends to be sporadic and inconsistent along the vein contacts and within the quartz, and the veins are not spaced closely enough to be considered a 'stockwork'.

Trenching and drilling of the prospect was initially carried out by Superior Molybdenum Company Limited in 1939 who estimated a probable molybdenite content of 0.24% Mo on a bulk sample. In 1964, geological and magnetometer surveys were completed by the Algoma Central Railway Company, and in 1965 International Nickel re-drilled the prospect. Previous assays taken by the Algoma Central Railway from several trenches across the main mineralized zone gave a re-calculated average of 0.13% Mo over a 30-foot (10 m) width, and the International Nickel diamond-drill holes, which were set to intersect below the vein system, encountered narrower and fewer quartz veins than on surface.

The Crane Tungsten Occurrence consists of a zone up to 9 m wide of white, irregular quartz veins contained within an enclave of schistose metaconglomerate bounded by massive granodiorite. The granodiorite adjacent to the schist is micro-fractured over a distance of about 75 m from the east contact, and the conglomerate has been metamorphosed to quartz-biotite and quartz-amphibole schist containing 10% to 15% quartzo-feldspathic and mafic clasts. Scheelite occurs as grains disseminated in quartz and at the contact between quartz and schist. Molybdenite and pyrite are commonly present.

Previous work on the property by Nickel (1952) for Crane Company Limited consisted of detailed geological mapping, extensive stripping, trenching, and diamond drilling (Assessment Files, Sault Ste. Marie Mining Division). Mineral processing tests were later carried out in 1950 by Quebec Metallurgical Industries Limited who determined an average concentration of 0.15% W from mineralized diamond drill core. Flotation concentrate contained up to 0.05 ounce gold per ton and 0.01% to 0.02% Mo. Tonnage was estimated at 790 tons per vertical foot (Nickel 1952).

A report of the results of field work will be submitted to the Ontario Geological Survey for publication in the Spring of 1986, as an open file report. It will consist of two regional scale maps at 1:253 000; one showing the locations visited, geochemical anomalies, and geological data, and a second showing geological and aeromagnetic data. Areas where reconnaissance geology was focused will be presented on two 1:15 840 scale map areas (the Kinniwabi Lake Map Area and the Millwood Map Area, Figure 9.3). As a result of 1984 field work, a Ba-Zn-Pb occurrence was discovered on Saymo Lake by D. Tortosa (Saymo Lake Barite Occurrence; Tortosa, in press). The prospect has been staked and trenched by Mr. C. Campbell who plans to carry out a diamond drilling program during the winter of 1985-86.

INDUSTRIAL MINERALS PROJECT

This project is a continuation of the industrial minerals, and building and ornamental stone inventory for the Sault Ste. Marie Mining Division, begun in

1984. The objectives of the inventory are to: 1) delineate target areas of suitable building or ornamental stone; 2) examine deposits with industrial mineral applications; 3) assess the economic potential of selected deposits; and 4) promote the unique stones found in the area. It is hoped that the results of this inventory will encourage exploration for these commodities.

Field work was supplemented by a literature search of both Federal and Provincial geological reports. Laboratory work consisted of slabbing, polishing, thin section analyses, and sieve tests. Test results and polished stone specimens may be viewed at the Resident Geologist's office in Sault Ste. Marie.

The following summarizes of the work done during the 1985 field season. More detailed results will be made available as an open file report in 1986. Figure 9.4 shows the locations of the areas described below.

Area 1 consists largely of granitic terrain accessible by Highway 129. All drivable side roads for a distance of about 80 km along this highway were traversed to carry out a reconnaissance survey of 21 townships.

In this area, 15 building and ornamental stone evaluations were carried out but no deposit was found to be suitable for this use. Although the area has an abundant supply of granitic rocks, where observed, they displayed one or all of the following unsuitable characteristics: 1) inconsistent grain size and colour over a large area; 2) intrusions of numerous randomly oriented pegmatite dikes of varying widths; and 3) fractures so closely spaced that quarrying would be impossible.

Two barite deposits within this granitic area were also visited: one near Frobel Lake in Casson Township and one near the Cheney Mine in Gould Township. Both were found to be small occurrences with little economic potential at this time.

An abandoned stone quarry was located in Rioux Township about 6 km northeast of Seymour Lake Road. Approximately 600 tons of a highly altered diorite have been removed from this site for use in local road construction.

Area 2 (Figure 9.4) extends from Echo Bay to Blind River and includes the north shore of Lake Huron and St. Joseph's Island. Most of this area is underlain by rocks of the Huronian Supergroup which were examined in 1984 for possible ornamental and industrial applications. Field work in 1985 was concentrated on a small area of granitic rocks in the southeast part of Area 2, and on a deposit of Cambrian sandstone near St. Joseph's Island. Five building stone evaluations were carried out in the granitic area; two exhibit suitable characteristics to be of potential value.

1. "Red Granite"

A red, potassic-rich, biotite granite (Robertson 1963) is situated in Thompson Township along the shore near Mississagi Bay. Joints were observed to be from 20 cm to 2 m apart with no preferred orientation apparent. The deep red colour and medium grain size are consistent over a large area, no deleterious minerals are present and the stone takes a fine polish. Potential reserves of this stone may be high, but drift cover makes assessment difficult.

2. "Pink Granite"

Several poorly exposed outcrops of massive, medium-grained, pink, biotite granite (Robertson 1963) were examined in Thompson Township, 8 km southeast of Dean Lake. Where exposed, the stone is relatively fracture free, grain size and colour are consistent, samples polish well and contain no deleterious minerals. The very attractive appearance of this stone when polished would warrant a more detailed examination of this area.

A deposit of silica sand was examined on Campement d'Ours Island near St. Joseph's Island, 50 km southeast of Sault Ste. Marie. The sand deposit can be followed along the southwestern shore of the island for a distance of approximately 500 m.

The sand is derived from the underlying Munising Formation which is a relatively clean, friable, quartz sandstone of Cambrian age. On St. Joseph's Island, the Munising Formation is overlain by Ordovician limestone. Much of the limestone cap has been eroded from Campement d'Ours Island, allowing disintegration of the Munising Formation.

Reserves of the Campement d'Ours silica sand deposit had previously been estimated to be between 800 000 and 2 000 000 tons of sand yielding a silica content in excess of 99% (Hewitt 1963). Field work in 1985 has shown that approximately 70 acres of the southern section of the island is overlain by the highly weathered Munising Formation, which in places is up to 16 m thick (Kral 1985). This is a very promising potential source of high quality silica.

Area 3 (Figure 9.4) extends north from Sault Ste. Marie for a distance of about 51 km. Three evaluations were conducted in this area and are described below.

1. Jacobsville Formation

The Jacobsville Formation is a red to white, medium- to fine-grained sandstone of Cambrian age. Beds range in thickness from 6 mm up to 1.5 m. Crossbedding and ripple marks are common features. Thin shale and siltstone interbeds are commonly present.

The Jacobsville Formation is exposed only sporadically from Sault Ste. Marie to Batchawana Bay, and good sections are difficult to observe (McConnell 1927). The sandstone is usually covered by a varying thickness of overburden; stripping would be necessary to establish a sizable quarry.

In the past, the Jacobsville sandstone has been well utilized as a building stone in Sault Ste. Marie, Ontario and Sault Ste. Marie, Michigan. Many attractive churches and business buildings are a testament to the durability of the stone. At the present time, a quarry with a licenced area of 8.3 hectares, located in section 17 of Tarentorus Township, is being operated on an intermittent basis by Mr. E. Koseba and Mr. R. Rancourt. They supply flagging, ornamental, and facing stone to the local area.

Coloured Maps	**OGS Geochemical Series Maps**	
2472	MAP 80756	

Potential reserves of the Jacobsville Formation sandstone are high.

2. "Black Granite"

A "black granite" is located in VanKoughnet Township, 30 km northeast of Sault Ste. Marie. It is a black-grey to black, massive, medium-grained, quartz diabase (McConnell 1927) which polishes well. Where examined, fracture spacing varied from 10 cm to 1.5 m. No sheeting was observed. Colour and grain size are consistent. Very minor amounts of pyrite are present (<1%) but no staining was observed.

Reserves are high, and the large area of the deposit (approximately 10 km long by 1 km wide by 66 m high) enhances the possibilty of finding a location suitable for quarrying. Further detailed mapping is planned for this deposit in 1986.

3. Kaolin

Two deposits of very low grade kaolin in altered Keweenawan felsite were examined on old Highway 17, near Mamainse, 50 km northwest of Sault Ste. Marie. These were found to be of little economic significance.

Area 4 (Figure 9.4) includes the granitic and greenstone terrain of the Michipicoten-White River region crossed by Highways 17N, 101, and 547. During reconnaissance work, begun near the end of the 1985 field season along the main highways, three potential building stone deposits were examined.

1. Quartz Gabbro

A small area of quartz gabbro (Sage *et al.* 1980) is located on a spur line of the Algoma Central Railway near Hawk Junction in Esquega Township. This stone has a striking appearance when polished due to a black matrix enclosing grey-green orbicules of plagioclase ranging in size from 3 mm to 2 cm. No deleterious minerals were observed. Joint spacing varies from 15 cm to 1 m. The deposit is small but provides excellent ornamental stone for the production of window lintels or table tops, if it is unsuitable as dimension stone.

2. Quartz Diorite

A massive, greenish white, medium-grained, quartz diorite (Srivastava and Bennett 1978) is located near the north shore of Dog Lake near Missinabie in West Township. Where observed, it is relatively fracture free and the colour and the grain size are relatively uniform. Preliminary results show the stone to polish well and further work is warranted to delineate the size of the deposit.

3. Biotite Granite

A large deposit of very pale grey, massive, fine-grained, biotite granite was examined on Highway 17 in Cecile Township, 12 km northwest of White River. The deposit is notable for the presence of a natural sheeting which is spaced from 0.5 to 1 m apart. A definite pattern of vertical joints is difficult to discern although the spacing varies from 20 cm to 1.5 m. Pyrite occurs in localized seams and lenses; however, areas were observed which were completely free of pyrite and further work is warranted to delineate these zones.

Although the stone polishes well, the colour may be too drab for a building stone but entirely suitable as a monument stone.

A display of the above-described rocks and minerals, as well as some of those reported on in Report of Activities 1984 (OGS MP 122), were displayed at the Ontario Geological Survey Open House in Toronto, in December, 1985.

The author dealt with three serious inquiries into ornamental stone, one for trap rock, and one for silica.

ONTARIO GEOLOGICAL SURVEY ACTIVITIES

P. Born and assistants carried out 1:15 840 scale geological mapping between Batchawana Bay and Goulais Bay, north of Sault Ste. Marie. The area mapped includes parts of Havilland, Tupper, Fenwick, and VanKoughnet Townships.

R.P. Sage continued the Ontario Geological Survey program of 1:15 840 mapping in the Wawa-Localsh area. The mapping of Abotossaway, Aguonie, and Bird Townships was completed, and most of Finan and Jacobsen Townships were mapped.

R.P. Bowen and J. Logothetis and assistants carried out 1:15 840 mapping in the Mishibishu Lake area during the 1985 field season. This is a helicopter-supported project and represents an effort by the Ontario Geological Survey to upgrade the geological mapping in an area of active mineral exploration.

K.B. Heather carried out detailed mapping of mineral occurrences and structural features in the Mishibishu Lake area during the 1985 field season.

G.M. Sirgusa and K.M. Chivers continued the Ontario Geological Survey's 1:15 840 scale geological mapping program in the Hemlo area. The area mapped is comprised of two contiguous rectangles, one rectangle extending along the Black River, north of Hemlo, and the second extending eastward toward the northern end of White Lake.

T.L. Muir continued a tectono-stratigraphic study in the Hemlo area in 1985. The area mapped includes the northern parts of Bomby and Lecour Townships.

A regional geochemical study of Michipicoten Island was completed under the direction of John A.C. Fortescue in August, 1985. During 1985 lakewater and sediment samples were collected from 94 locations on the island.

In September 1985, J.A.C. Fortescue and J.R. Webb continued a study of geochemistry and remote sensing data from parts of Home and Raaflaub Townships in the Montreal River area, and parts of Gap, Gaudry, Lunkie, and Nahwegezhic Townships in the Cowie Lake area.

Quaternary mapping in the Hemlo area continued in 1985 under the direction of R.S. Geddes. This year mapping was concentrated on the map sheets of Marathon (NTS 42 D/9), Manitouwadge (NTS 42 F/4), and White River (NTS 42 C/11).

Rainer R. Wolf completed mapping of the Paleozoic Geology of Cockburn Island in the North Channel of Lake Huron during the summer of 1985. Supplementary stratigraphic information was obtained from a test drillhole drilled in September of that year.

The preliminary results of the projects listed above and other field work carried out in 1985 by the Ontario Geological Survey, can be found in the Summary of Field Work and other Activities 1985, by the Ontario Geological Survey (MP 126).

10. Sudbury Resident Geologist Area, Northeastern Region

W. Meyer[1], R.W. Campbell[2], R. Adlington[3], and F.H. Toews[3]

[1]Resident Geologist, Ontario Ministry of Northern Development and Mines, Sudbury

[2]Resource Geologist, Ontario Ministry of Northern Development and Mines, Sudbury

[3]Contract Geologist, Ontario Ministry of Northern Development and Mines, Sudbury

INTRODUCTION

The Sudbury Resident Geologist's area encompasses about 28 000 km^2 (Figures 10.1a and 10.1b). Geologically it can be divided as follows:

Paleozoic: Ordovician and Silurian marine sediments on Manitoulin and several smaller islands. These underlie about 18% of the area.

Proterozoic: Grenville Province. About 33% of the area belongs to the Grenville Front Tectonic Zone and Central Gneiss Belt; 160 km of the Grenville Front lie within the area.

Proterozoic: The Sudbury Igneous Complex and Whitewater Group sedimentary rocks cover about 4% of the area.

Proterozoic: Southern Province. Clastic sediments, volcanic rocks, and diabases of the Huronian Supergroup underlie about 21% of the area.

Archean: Granites, gneisses, and greenstones (volcanic-sedimentary belts) of the Superior Province underlie about 24% of the area. The granite to greenstone ratio is about 19:1.

Glacial till and organic overburden covers much of the bedrock.

The area is well known for its large nickel-copper-precious metal mines, many gold and base-metal prospects, and enigmatic geological features. These draw many companies, prospectors, and visitors to the area each year.

STAFF

Staff positions and changes in 1985 were as follows:

P.E. Giblin was Regional Mineral Resources/Land and Waters Coordinator for all of 1985.

J.M. Martins resigned as Acting Resident Geologist in early January.

W. Meyer held a contract position from the beginning of the year, and became Resident Geologist on August 26.

R.W. Campbell held a contract position from January 21 to October 2, when he became Resource Geologist.

R. Adlington worked on contract in the office from January to June, and from October to December. For three months he was assisted by M. Charette, R. Degagne, K. Lacey, and R. MacNeil.

F.H. Toews started a two-year investigation of gold mineralization between Sudbury and the Espanola area. Two senior assistants, M.E. Grant and M. Napoli, helped with field and office work, and three junior assistants, D. Beilhartz, M. Charette, and D. Pilkey helped with field work.

S. Scott was office and field assistant during the summer months.

Y. Paquette retired at the end of October, after having been secretary to the Resident Geologist for 23 years. T. Livingstone then filled that position on contract.

STAFF ACTIVITIES

SUMMARY

Staff of the Resident Geologist's office visited properties and areas of problematic geology, collected drill core, guided tours across the Sudbury Structure and Grenville Front, assisted prospectors and mining company personnel with office researches, mineral identification, and field problems, talked to Junior Rangers, and worked on four special projects which are more fully described below.

By the end of November, 319 people had visited the office.

GOLD STUDY EAST OF WANAPITEI LAKE by W. Meyer

This started out as a thin section study early in 1985 on altered rock from a drill program in Scadding Township. The drilling was carried out by Arthurian Resources Limited on a 20-claim property optioned from P. Brown of Corbeil, Ontario. The property lies 4 km northwest of the Scadding mine, then operated by Westfield Minerals Limited. The alteration is similar to that at the Scadding mine.

The thin section work produced few results, and during spring and summer, the study expanded into a regional reconnaissance east of Wanapitei Lake to gain a better understanding of the distribution of the alteration, its geometry in relationship to the host rocks, and the relationship to gold mineralization. The problem became more intractable as time went on, and work will continue in 1986. The following observations can be made:

1. A fine-grained pink alteration is widespread east of Wanapitei Lake. It also occurs north and south of the lake, but is less common there. It is not known if the alteration occurs on the western side of the lake, and thus right around it.

   The pink alteration was seen to affect all Huronian formations from Bruce to Lorrain, and Nipissing Diabase. Thin section work and field relationships suggest that it is a metasomatic change from incipient to complete replacement. Bedding and crossbedding may be well preserved, and ghost pebbles can be seen in altered Bruce Formation paraconglomerates.

The alteration consists of a quartz-albite mosaic, with grains mostly in the low micron range. Analyses from the Scadding mine (Martins *et al.* 1979; D.G. Innes, Quinterra Resources Incorporated, personal communication, 1985) suggest soda metasomatism, but the analyses were not compared with analyses of unaltered and stratigraphically equivalent rocks. Flag Resources Limited analyzed several samples from Rathbun Township, and obtained between 8% and 12% Na_2O (R. Goad, Consulting Geologist, personal communication, 1985).

The geometry of the alteration is difficult to pin down. Between the Scadding mine and Wanapitei Lake it lies along the Espanola-Serpent Formations contact, so that it appears stratabound for 6 km. However, it pinches and swells from nothing to perhaps 150 m thick, so that on a smaller scale it rapidly crosscuts bedding. One possible explanation is that solutions rose along steeply dipping faults or breccia pipes, and spread laterally along the Espanola-Serpent Formations contact. Elsewhere, the alteration occurs in irregular masses several hundred metres across, or as dike-like features.

East of Wanapitei Lake, the alteration affects Sudbury Breccia, and is cut by olivine diabase dikes. The age of the alteration is therefore most likely to be between 1.85 Ga and 1.2 Ga. Martins *et al.* (1979) and Harper (1983) thought that the alteration relates to Nipissing Diabase, i.e. is about 2.16 Ga old. Most probably it is younger.

2. An iron rich rusty weathering carbonate often replaces the pink alteration in the form of well developed rhombohedra. These range from microscopic size to crystals 40 mm across. The rhombs may be randomly scattered in the pink rock, or lie along well defined planes, which give the rock a well stratified appearance. In some outcrops, these planes are parallel to regional strike and dip of unaltered rock, and thus probably are bedding planes.

   Carbonate rhombs may be developed in such numbers that they coalesce to form a very coarse, near-massive rock, with only some interstitial pink material remaining. Massive replacement carbonates several metres thick occur. These also occur in brecciated but otherwise unaltered country rock, mostly the Serpent Formation.

   The source of the carbonate appears to have been the Espanola Formation, but the recrystallized carbonate is richer in iron.

3. At the Scadding mine, gold occurs in massive chlorite and pyrite within brecciated pink rock. Where chlorite is developed, carbonate rhombs are scarce. Some chlorite at the mine occurs in well shaped rhombs, thought to be pseudomorphs after carbonate.

   The source of the widespread pink alteration, the reasons for subsequent carbonate recrystallization, the causes of the still later but more localized brecciation, chloritization, pyritization, and gold mineralization, are as yet unknown.

THE TEMAGAMI MAGNETIC ANOMALY by R.W. Campbell

The Temagami magnetic anomaly is a large elliptical feature that occurs between Lake Wanapitei and Lake Temagami. It strikes northeasterly for 58 km and is 19.3 km wide. Totally or partly, it underlies 17 townships. It occurs along a structure which contains several other magnetic anomalies of similar magnitude. This structure trends northeasterly parallel to the Grenville Front and is marked by several major fault zones. To the southwest, the Great Lakes Tectonic zone connects with the Murray Fault zone which connects with the Huronian-Mistassini Fault zone. This same trend appears as a relative gravity high on the Bouguer Gravity Anomaly Map of Canada.

The northeastern part of the anomaly can be attributed to several outcropping wide bands of Archean Algoma-type oxide iron formation. The southwestern part of the anomaly is overlain by thick Huronian sediments, in places >1524 m. Gravity and magnetic interpretations suggest the southwestern part may be caused by an alkali intrusive complex.

The occurrence of eugeosynclinal Archean rocks overlain by Huronian shallow marine sediments implies a paleo-depression. The fact that this paleo-depression lies along a northeasterly trend of similar magnetics, gravity and geology allows for the speculation that the entire trend may have been a depression, possibly representing an ancient rift or subduction zone during Precambrian time.

Drillhole data from the study area indicate a progressive down faulting of the Archean crust from Lake Temagami to Lake Wanapitei. Just west of Lake Wanapitei, windows of Archean greenstone are again noted. This may represent a transverse graben structure into which the Gowganda and Lorrain Formations were deposited. This is also implied by the basinal appearance of the Lorrain Formation northeast of Lake Wanapitei.

The study area is cut by many fault systems. Many of these systems appear to have been active over a long time. The most prominent of these systems strikes approximately N65°W and is generally filled with Keweenawan olivine diabase. Felsic intrusions played a major role along with the faulting in disrupting the continuity of the Archean stratigraphy, making it difficult to extrapolate the Archean under the Proterozoic cover.

Profiles of the magnetics show a general broadening and smoothing of the anomaly from east to west. Drillhole data and geological observation indicate the Archean basement is exposed in the east and is buried by at least 1524 m of Huronian sediments in the west.

At the moment, many possible explanations can be offered for the Temagami magnetic anomaly. The eastern part may be solely related to the iron formations. The central part of the anomaly between Eagle Rock Lake and Rawson Lake Fault may be related to deeply buried iron formation or a deeply buried mafic to ultramafic body or both.

To the west of the Rawson Lake Fault, the gravity survey suggests rocks of density 2.65 to 2.70 t/m

- ▨ Boundary of Resident Geologist's Area

(V.K. Gupta, Geophysicist, Ontario Geological Survey, Toronto, personal communication, 1985). These rocks could be felsic to intermediate intrusions or gneissic rocks. The magnetic survey indicates a possible separate anomaly source over this section of the study area. It is possible that the southwestern end of the Temagami magnetic anomaly is represented by an alkali intrusive complex.

Much more study is required on the area. Planned for this winter is more technical research on similar anomalies and examination of samples taken during the 1985 field season. A more intense field study will be carried out in 1986.

PRECIOUS METAL STUDY: SUDBURY-ESPANOLA AREA by F.H. Toews

In June 1985, a two-year project was initiated to study precious metal occurrences in the Sudbury-Espanola area. The aim of the project is to examine in detail, sample, and interpret known gold prospects and former, small, producing mines found within parts of the Huronian Supergroup.

Upon completion of field and laboratory studies, ideas on the environment, genesis, and exploration prospects for these precious metal occurrences will be forthcoming in an open file report. This, in turn, will assist (and hopefully stimulate) the exploration for precious metal deposits in the area.

During the 1985 field season, properties hosting 14 precious metal (predominantly gold) occurrences were mapped on grid lines at a scale of 1 inch to 100 feet. More than 1000 grab and chip samples were collected to encompass both the vein zones and the surrounding host rocks. A portion of the lithogeochemical samples collected are in the process of being analyzed for both major elements and trace elements (As, Au, Ag, Pt, Pd) by the Geoscience Laboratories, Ontario Geological Survey, Toronto. As well, a number of thin and polished sections are to be prepared for examination. Structural data collected during mapping will also be interpreted.

The properties examined are located in an east-west trending zone extending through McKinnon, Mongowin, Curtin, and Roosevelt Townships (Figure 10.2). Some of the gold occurrences have been known since the early 1900s and the McMillan and Bousquet Mines were small producers in the mid-1930s (Gordon *et al.* 1979).

The gold occurrences are of the vein type, comprising stockwork to quartz breccia to massive quartz with a variable content of carbonate, sulphide minerals, chlorite, and hematite. The veins occur in vertical to steeply dipping metasediments of the Gowganda Formation (quartzites interbedded with pelites and paraconglomerate) and underlying Serpent Formation (quartzites). Some of the gold occurrences (i.e. Evangeline Lake area, lot 12, concession 4, Mongowin Township, McMillan Mine, and possibly the Fox Lake prospects) are found on the southern limb of the Fox Lake Anticline as defined by Robertson *et al.* (1972) and Card (1975). Auriferous veins may also occur at, or near, the contact with Nipissing Diabase and/or amphibolite intrusions (e.g. Bousquet Mine, McMillan Mine, Bob Tough prospect, Howry Creek Mine, Hanwood-Leech Lakes area); in close proximity to the major east-west trending Charlton Lake Faults (e.g. Evangeline Lake area, Howry Creek Mine); and to the northeast-trending Fox Lake and Hardwood Lake Faults (e.g. Fox Lake prospects) as defined by Robertson *et al.* (1972) and Card (1975). Northwest-trending lineaments or faults are also present in the vicinity of most of the gold occurrences. Drag folding of pelitic rocks appears to be associated with auriferous quartz veins at the McMillan Mine (Rickaby 1936).

Commonly, the environment surrounding the quartz veining shows the effects of carbonatization and silicification which occur in both the metasediments and the mafic intrusions. Sulphide minerals (arsenopyrite, pyrite, and/or pyrrhotite), hematite, and chlorite can also be found in the wall rocks.

The one prospect examined which contains platinum group elements (PGE) is located in central Curtin Township. This occurrence is hosted by a steeply dipping, east-west trending, sill-like body of Nipissing Diabase which is intrusive into, and grossly conformable to, the enclosing interbedded quartzites, pelites, and conglomerates of the Gowganda Formation. Locally, the Diabase contacts crosscut stratigraphic contacts of the metasediments; show brecciation and stoping of the metasediments; and, along part of the northern margin, the buried (fault?) contact is bounded by a 60 m wide, northwest-trending zone of brecciated quartzites, pelites, and conglomerate impregnated by quartz veining and by Sudbury-type breccia. Gabbroic fragments are present locally in the breccia veins and amphibolite dikes are also present in the gabbro body at this prospect. In places, pyrrhotite, chalcopyrite, and/or pyrite occurs disseminated and chalcopyrite as fracture fillings in the gabbro.

Sulphide minerals can occur in both the unsheared and the sheared zones which may be accompanied by silicification and carbonatization. PGE and gold are associated with the sulphide minerals (Assessment Files, Resident Geologist's Office, Ministry of Northern Development and Mines, Sudbury).

GEOLOGICAL DATA INVENTORY FOLIOS (GDIFs) by R. Adlington

By the end of 1984, 51 GDIFs had been published and 2 more completed. In 1985, 29 GDIFs were published and 5 more completed.

Many visitors to the Sudbury office are unaware of GDIFs and their usefulness.

A GDIF is useful to mineral exploration companies, individual prospectors, mineral collectors, and anyone interested in mining history because it provides a summary of Assessment Work Files and mineral deposits information.

The data are compiled on a township by township basis. All data are plotted, and then correlated, on a township map at the same scale as a claim map. Property locations are plotted on a separate map at the same scale.

Text pages (forms) summarize additional information which, where applicable, is cross-referenced to the two maps.

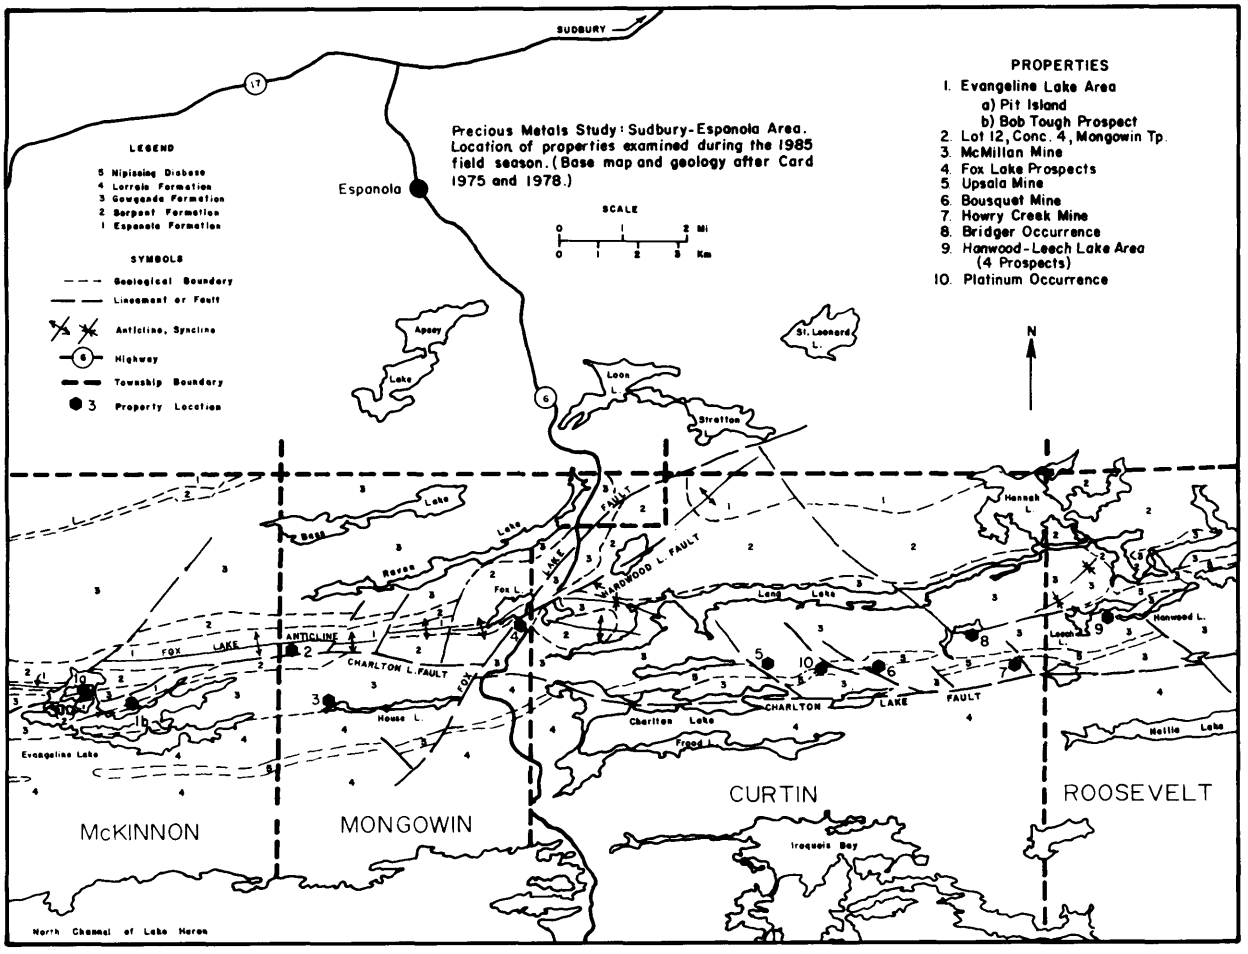

Figure 10.2 . Precious metals study : Sudbury - Espanola Area

A GDIF has several advantages. It saves time and work when searching for data in a township, particularly about an individual company or property.

All information is summarized, compiled, and correlated.

The person searching can locate the area of interest quickly and, if more detail is required, can go directly to the sources of information.

A glance at the data map shows areas of high interest and reported assessment data.

The GDIF is easily up-dated and reissued.

MINING ACTIVITY

Nickel-copper-precious metal mining by Inco Limited and Falconbridge Limited continued to dominate mining in the area. Other commodities produced are silica, dolomite, sand, and gravel. Three old mines are being reopened to assess if they are viable gold producers.

NICKEL-COPPER-PRECIOUS METALS

Inco Limited operated nine underground mines, two open pits, three mills, one smelter, two refineries, and a metal strip plant for coinage blanks. Falconbridge Limited operated six underground mines, two mills, one small open pit, and one smelter in the area (Figure 10.3).

Both companies were profitable for the first nine months of 1985 but continuing low copper prices and the sliding nickel price from US $2.58 in the second quarter to below US $2.00 in the last quarter is causing concern. Both companies announced further staff cuts.

GOLD

Three companies looked at three small idle gold mines to see if these can be reopened.

The Scadding mine in Scadding Township remained closed in 1985. In 1984, it produced 3525 ounces (109.6 kg) of gold from 24 000 tons of ore from three small open pits. An underground orebody has not been developed.

15. McCreedy West Mine
16. Stobie Mine

During the year, Orofino Resources Limited gained control of the mine from Westfield Minerals Limited. Orofino Resources Limited entered into a 50:50 joint venture with Groundstar Resources Limited to drive a 1500-foot (457 m) decline to explore gold-copper mineralization on the Norstar property in Davis Township, 9 km east of the Scadding mine. Work on the portal started in October.

Previous owners reported 80 000 tons of 0.2 ounce gold per ton (6.88 g/t) and 0.86% copper. If mineable reserves are found, ore will be trucked to the 200-ton per day mill at the Scadding mine. Orofino Resources Limited will manage the program.

Emerald Lake Resources Incorporated reported proven and probable reserves of 1 926 500 tons of 0.204 ounce gold per ton (6.34 g/t) in the Golden Rose Mine in Afton Township, and more than 1 million tons of possible reserves.

In November and December, the company dewatered the upper levels to extract a bulk sample for metallurgical testing.

Loki Resources Incorporated gained control of the old McMillan Gold Mine in Mongowin Township from Hemlar Resource Explorations Limited. The mine has a 650-foot (198 m) shaft, an internal winze, and 7 levels to 875 feet (267 m). During the 1930s, 10 593 ounces of gold (329.5 kg) were won from 60 139 tons of ore. Reserves are estimated to be 500 000 tons grading 0.18 ounce gold per ton (6.2 g/t) to the fifth level at 600 feet (183 m).

By the end of November, Loki Resources Incorporated had dewatered the mine to the fifth level, and was preparing to systematically sample the mine.

INDUSTRIAL MINERALS

Indusmin Limited reported 460 000 tons of silica produced from their Badgely Island quarry in Georgian Bay. Silica is being quarried from orthoquartzites of the Bar River Formation.

Manitoulin Dolomite Limited continued to quarry dolostone of the Amabel Formation from the western end of Manitoulin Island. Production figures were not available.

Warren Industrial Feldspar Company Limited continued its examination of a building stone prospect in Henry Township, 50 km east-northeast of Sudbury. Test samples have been polished and examined. At the moment, the company is conducting a market study and looking into using black anorthosite as curbing.

Canadian Unique Granites Limited is examining a building stone prospect in the southeastern corner of Goschen Township, 43 km south of Sudbury. They are examining a pink feldspar porphyry with a dark matrix, and an equigranular pink granite. The prospect has had favourable reports from a consulting firm and at the moment is being drilled to determine horizontal sheeting.

A few areas are being looked at close to Sudbury for use as silica flux.

EXPLORATION ACTIVITIES

Low metal prices took their toll, and claim staking decreased by one third. Between January 1 and November 30, 1985, 920 claims were staked, as compared to 1373 in the same period of the year before.

Figure 10.4 compares staking activity from 1973 to the end of 1985.

The most active search areas were for gold north and east of Wanapitei Lake, and for base metals northwest of Sudbury. Assessment Work filed in 1985 is listed in Table 10.1 and Exploration activity is summarized in Table 10.2. Some of the properties visited, and highlights known to this office are as follows:

Noranda Exploration Company Limited, the major ground holder in the Benny Greenstone Belt, contracted a detailed airborne survey of their claim group last spring. During the field season, they followed up with reconnaissance geological, geochemical, and geophysical surveys.

Federal Kirkland Mines Limited and Stralak Resources Incorporated continued to drill their multizone zinc-lead deposit in Craig Township. Preston East Dome Mines Limited in 1952 had outlined 363 680 tons grading 3.18% zinc, 0.32% copper, and 0.68 ounce silver per ton over an average width of 2.5 m to a depth of 47 m. Values as high as 22% zinc were encountered in the east zone. Federal Kirkland Mines Limited and Stralak Resources Incorporated have outlined approximately 750 000 tons proven or inferred ore ranging from 6 to 17 feet wide grading 3 to 22% zinc, 2 to 12 ounces silver per ton, 0.5% lead, and 0.5% copper (The Northern Miner, July 11, 1985). Both the old east zone and the new east zone are open. Drilling is scheduled to continue in early 1986 (D. Constable, Consulting Geologist, personal communication, 1985).

Hecla Mining Company has the Wolf Lake gold property in MacKelcan Township under option from Flag Resources Limited. This property had been drilled intensively in the years before. In early 1985, Hecla Mining Company added five holes, drilled from ice on the lake. The full core length of the program is not known. One vertical hole drilled to 1067 feet (325 m) and bottomed in altered Lorrain Formation arkoses. The breccia zone appears to be wide and deep under the lake. The Northern Miner reported results on the first three holes. One section assayed 0.7 ounce gold per ton (24 g/t) over 1 foot (30.48 cm), and several 10 to 15 foot (3 to 4.5 m) sections grading between 0.105 and 0.166 ounce gold per ton (3.6 to 5.7 g/t). Hecla Mining Company plans further drilling in 1986.

In early summer, Flag Resources Limited stripped, trenched, mapped, and diamond drilled a complex breccia and alteration zone on the southeastern shore of Boot Lake in Rathbun Township. The exposed part of the zone is about 300 m long and 120 m wide, with the long axis trending north-northeast. The breccia and alteration look similar to that of the East-West Zone at the Scadding mine.

In late summer, Flag Resources Limited discovered a linear dike-like pink alteration zone in

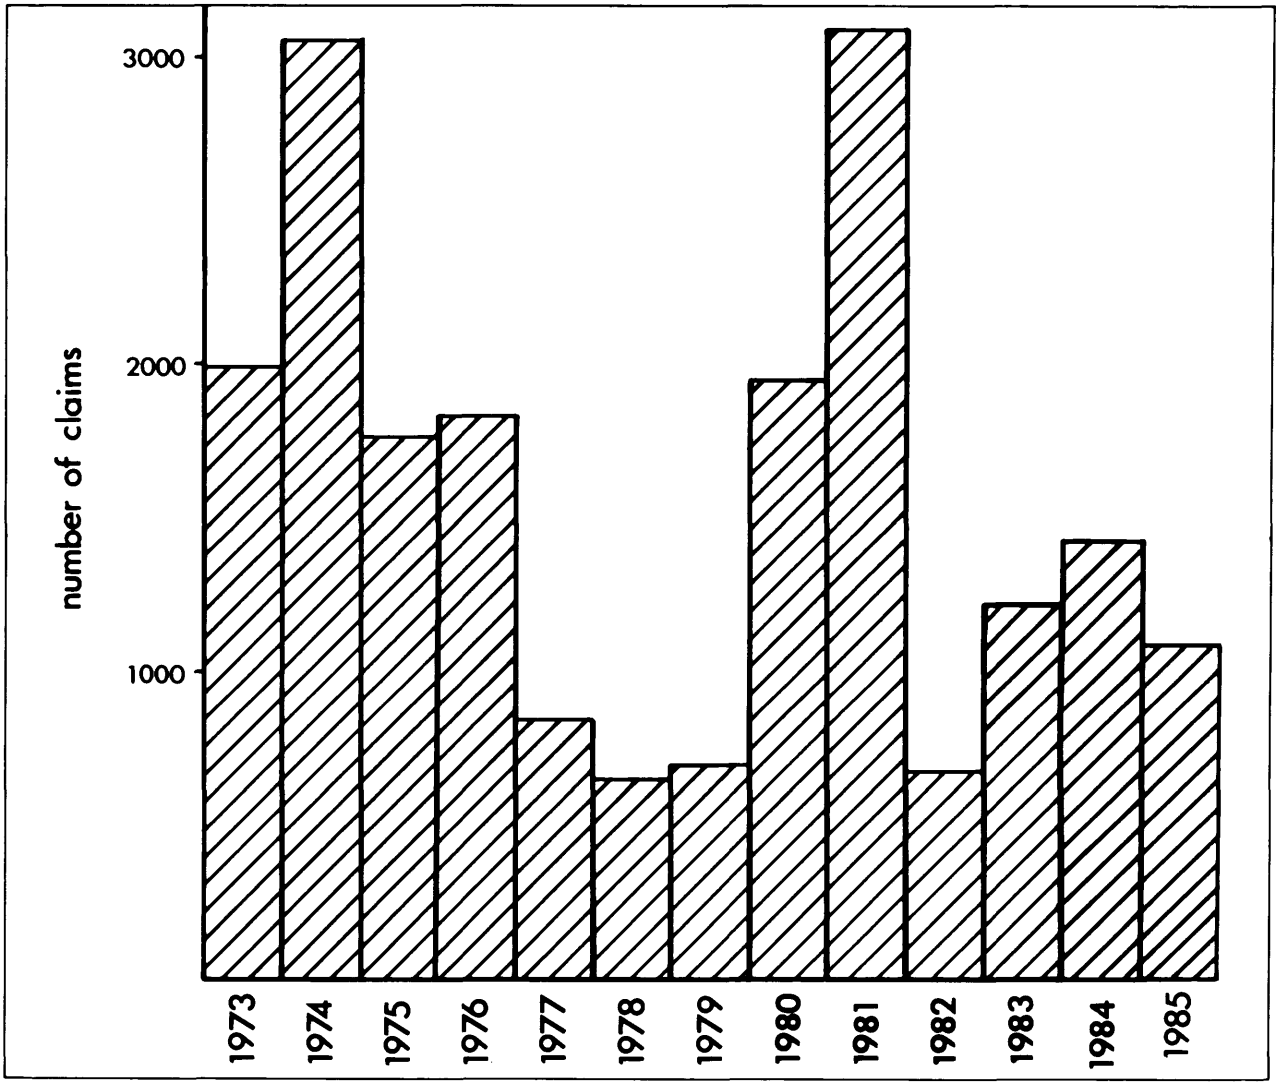

Figure 10.4 . Claim staking activity, Sudbury Mining Recorders Office.

Gowganda Formation sediments in Rathbun Township. The zone is up to 40 m wide, and can be followed for about 1700 m in a northwesterly direction from near the old Mondoux mine. The structure was mapped and sampled. Surface samples assayed up to 0.3 ounce gold per ton (10.3 g/t). Flag Resources Limited drilled five angle holes into the zone. The best assay value reported is 1.7 g Au/t over 1 m.

Jedburgh Resources Limited holds 127 unpatented claims in Hart Township. Huronian outliers here contain zinc, silver, cobalt, and magnetite mineralization in Espanola Formation limestones. Two zones are known. In 1985, Jedburgh Resources Limited carried out soil sampling, VLF and magnetometer surveys, trenching, mapping, and diamond drilled 1515 m in 26 holes. Zinc values of up to 4% in mineralized sections of up to 3 m wide were encountered.

W. Klenk continued to work on old oil wells in the Pike Lake and Manitouwaning areas of Manitoulin Island to see if additional oil can be recovered. Klenk had government support under the NORDEV program.

ONTARIO GEOLOGICAL SURVEY ACTIVITIES

Publications released in 1985 by the Ontario Geological Survey that relate to the area are listed in Table 10.3.

PRECAMBRIAN GEOLOGY PROGRAMS

C. Marmont and five assistants mapped Venturi and Tofflemire Townships, and the northern half of Vernon Township. These townships form part of a large unmapped area 60 km west of Sudbury.

P. Bröckmeyer and R. Lakomey, students from the University of Muenster, Federal Republic of Germany, worked on Footwall Breccia and the basal Onaping Formation in Dowling, Levack, and Morgan Townships.

B.O. Dressler continued mapping in Falconbridge and Street Townships.

ENGINEERING AND TERRAIN GEOLOGY PROGRAMS

R.R. Wolf mapped Cockburn Island in Lake Huron. A stratigraphic drillhole to 521 m augmented surface data. Precambrian basement was intersected at 483 m.

G. Jones and assistants carried out aggregate resources inventories northwest of Sudbury, and west of Espanola.

GEOPHYSICS/GEOCHEMISTRY PROGRAMS

V.K. Gupta used aeromagnetics to interpret depth to basement and the distribution of Nipissing Diabase in the Cobalt Plate.

ONTARIO MINERAL EXPLORATION PROGRAM (OMEP)

Eleven OMEP agreements were in force for all or part of 1985. Planned total expenditures were to have been $2,727,750. If all this money is spent, OMEP will reimburse $582,936 of this.

ONTARIO GEOSCIENCE RESEARCH PROGRAM

Three projects, funded by the Ontario Geoscience Research Grants Program, lie wholly or partly within the area of the Sudbury Resident Geologist.

A.J. Naldrett, B.V. Rao, N.M. Evensen, and B.O. Dressler worked on the Sudbury Structure; D.J. Wright and B.R. Rust studied stratigraphy and sedimentology of the Bar River Formation, Huronian Supergroup; and D.M. Canrod and A.J. Naldrett studied petrology, geochemistry, isotopes, and PGE potential of Nipissing Diabase.

CORE LIBRARY

Sudbury is still without a core storage facility. During the year, Hecla Mining Company donated core from their 1985 Wolf Lake gold drilling program (complete and condensed); Jedburgh Resources Limited from their Hart Township base-metal drilling program (complete and condensed); and Flag Resources Limited from their Boot Lake gold drilling program in Rathbun Township (condensed).

The complete core is temporarily stored at McFarlane Lake, and the condensed sections are temporarily stored in the Resident Geologist's office.

11. Huntsville Resident Geologist Area, Algonquin Region

David J. Villard[1] and Mary Garland[2]

[1] Resident Geologist, Ontario Ministry of Northern Development and Mines, Huntsville

[2] Geologist, Ontario Ministry of Northern Development and Mines, Huntsville

INTRODUCTION

Permanent staff in the Huntsville Resident Geologist's office consist of Jack van der Meer, Mineral Resources Coordinator, David Villard, Resident Geologist, and Kathy Martin, Secretary. Mary Garland continued on a long-term contract, and worked mainly on mineral characterization studies. The boundary between the Bancroft Resident and the Huntsville Resident Geologist was adjusted to be more reflective of geology.

Exploration activity increased during 1985, and was related mainly to work carried out on two graphite properties. Besides graphite, interest was shown in gold, base metals, stone, rare earths, gemstones, and silica. Claim staking was at its highest level in several years.

RESIDENT GEOLOGIST'S ACTIVITIES

The Algonquin Region, for mineral management purposes, is divided into two areas of responsibility. The Huntsville Resident Geologist is responsible for the northwestern half of the Region as shown on Figure 11.1. In 1985, the boundary between the Huntsville Resident and the Bancroft Resident was adjusted to be more reflective of geology. The Huntsville Resident is now responsible for that part of the Central Gneiss Belt lying within the Algonquin Region.

As in previous years, much of the Resident's time was spent on consultative duties, with requests for information or assistance coming from prospectors, exploration people, and the general public. The year 1985 showed a modest increase in the number of public inquiries. Graphite, silica, gold, copper, and stone were the commodities for which information was most requested. All of the active properties, as well as many inactive areas, were visited at least once during the year.

Mary Garland continued her study of the graphite potential of the Central Gneiss Belt, as well as initiating a study of the stone potential of the same area. The graphite study is almost completed and a report should be published early in 1986. Her work on stone was limited to an inventorying (field and office) of the known "stone" occurrences within the Central Gneiss Belt.

Two out-of-Province trips were organized during 1985, both directly related to the "stone" project. Three days were spent in the Quebec City-Eastern Townships area with L'Association des Producteurs de Granite du Québec Inc. Several "granite" quarries and finishing plants were visited, enabling geological staff to develop a good understanding of the building stone industry in Quebec. A trip was also made to the state of Vermont, where various marble and granite operations were examined.

In 1985, a joint project was undertaken with the Eastern Region, Ministry of Natural Resources, to develop an overview of the building stone potential of the Grenville Province. Several months of well conducted field work were devoted to the Central Gneiss Belt, and several interesting areas, deserving additional work, were outlined by C. Verschuren and C. Papertzian, of the Tweed Resident Geologist's office. The Huntsville office will continue this work in 1986.

A project to computerize most of the geological data in the Huntsville office was initiated, with the purpose to provide a better service to the exploration industry, and better utilization of data internally. The system is expected to be fully operational in 1986.

GRAPHITE PROJECT

All field work has been completed on this project, as well as basic thin section work and preliminary chemistry. A detailed study of the graphite flake is currently in progress. The graphite was separated by flotation and magnetic separation methods, and then sieved. Flake finer than 100 mesh is not used. The graphite will be analyzed by neutron activation, Isotrace, ICP, SCEM, and reflecting light microscope. Preliminary neutron activation work was done in the summer to check the feasibility of this method, and will be followed by more runs during the winter. A major problem with sample homogeneity and purity was encountered. The nature of the graphite flake traps quartz and feldspar grains between the layers, and these grains can be very difficult to remove. Comparative work on Isotrace, the ICP mass spectrometer, and the SCEM, will yield data to determine which method is most suitable to use. The results of the work on flake graphite and the deposits will be published as an open file report in the spring of 1986.

COMPUTERIZATION OF MINERAL AND GEOLOGICAL DATA

A study was initiated that will result in the computerization of most of the geological and mineral deposit information in the Huntsville office. R. Dubien, the systems officer in the Algonquin Region, is completing a program to utilize d-Base III on an IBM-PC. This program should allow for the easy and efficient retrieval of data, the manipulation of data and possibly using the system to help the prospector and exploration geologist in their search for viable mineral deposits. It is hoped to have this system fully operational, with most data on board, by April 1, 1986.

OTHER GEOLOGICAL ACTIVITIES

LESLIE M. FROST NATURAL RESOURCES CENTRE

R. Keevil, Acting Lands and Minerals Specialist at the Frost Centre, reported that over 5000 visitors participated in tours and lectures during 1985. An inventory of potential sites for lapidary stone was carried out; 30 sites were evaluated. Results of this inventory are available for viewing at the Centre. A reconnaissance peatland/wetland inventory was also carried out. The report is under review.

The Centre also helped in the preparation of rock samples for projects carried out in the Huntsville office.

PEAT

A private-land agricultural peat extraction operation commenced in Strong Township during late summer, with approximately 9000 cubic yards stockpiled before freeze-up, for shipping in spring, 1986.

A project, to demonstrate the viability of peat as an energy alternative, was carried out through a tripartite agreement between the District Municipality of Muskoka (proponent), the Ministry of Natural Resources, Algonquin Region (project manager), and Canada Works (Section 38, Ontario Resource Sector Work Program). The product accruing from this project is to be tested at various Ministry of Natural Resources and private sector facilities during the winter of 1986-87. A sod peat extruder was designed and built, and approximately one ton of peat sods was produced before freeze-up.

The District Municipality of Muskoka, the Ministry of Agriculture and Food, the Ontario Government Interministerial Committee on Peat, and the commercial cranberry producers of Muskoka, have met to consider the expansion of cranberry production in the area. The Ontario Geological Survey has provided assistance to this project by supplying peat and peatland inventory data derived from Open File Report 5488, "Peat and Peatland Inventory of the Parry Sound Area".

ONTARIO GEOLOGICAL SURVEY

M.J. Ford of the Engineering and Terrain Geology Section continued work on a guidebook of surficial geological features within Algonquin Provincial Park. Some general information on bedrock geology will also be included.

GEOLOGICAL SURVEY OF CANADA

K. Ford of the Radiation Geophysics Section continued work on the Allan Lake Carbonatite in the northeastern corner of Algonquin Provincial Park. In 1985, two diamond-drill holes of approximately 325 m each were drilled from either side of a small unnamed lake about 2 km east of Allan Lake. The holes were drilled at an angle of 45° underneath the lake. The upper part of each hole consisted of bands of gneiss and carbonate "veins". "Massive carbonatite" was encountered in each hole, corresponding to a downward projection of the lake-shoreline boundary, suggesting that the subcircular lake may be reflective of the pluton's shape.

A. Davidson of the Superior-Grenville Section continued mapping the Grenville Province between Latitudes 45°N and 46°N, concentrating his effort within the interior of Algonquin Provincial Park.

EXPLORATION ACTIVITY

As of December 2, 1985, a total of 123 claims were recorded in the Algonquin Region, a noticeable increase from the 20 recorded in 1984. Claim staking is not necessarily a true indication of exploration activity, as a significant proportion of the land base is patented, where staking is not required.

Exploration activity related to interests in graphite, gold, base metals, rare earths, stone, gemstones, and silica is shown in Figure 11.1, and Tables 11.1 and 11.2.

One of the major drawbacks to exploration in the Algonquin Region is the almost complete lack of a geological data base. Hopefully this will begin to be rectified with the initiation in 1986 of several projects under the Federal-Provincial Minerals Agreement. Proposed work calls for Precambrian mapping in the area northeast of Parry Sound; surficial mapping (incorporating a geochemical component) in the area around and north of, Parry Sound; mineral deposit studies and limited aggregate assessment studies in the Muskoka-Parry Sound areas.

GRAPHITE

Exploration for graphite was active on two properties in 1985. In Maria Township near the northeast corner of Algonquin Provincial Park and in Butt Township, east of Kearney, significant drill programs were carried out to outline reserves.

In Maria Township, 101 holes have been drilled to date. According to a company news release on August 15, 1985, "the exploration and development program will consist of infill drilling in the main ore zone, step out drilling in the adjacent mineralized areas, bulk sampling, and metallurgical testing. In conjunction with the bulk sampling and metallurgical testing, detailed pilot plant work will commence, as well as pit planning, base line environmental studies and infrastructure assessment" (Princeton Resources Corporation News Release, May 7, 1985). By December 1, 1985, most of the planned drilling had been completed, and the site had been prepared for installation of the pilot mill and removal of the bulk sample. The company plans to have the pilot mill operational by January, 1986, testing milled flake and sending flake to potential consumers. A production decision is expected sometime in 1986.

In Butt Township, Erana Mines Limited conducted additional drilling and sampling on the Graphite Lake property. A 225-ton bulk sample has been removed from the property for additional testing.

The extensive exploration carried out on the above described properties is encouraging, since graphite has not been mined in Ontario for many years. Both companies anticipate that their properties will make it to the production decision stage in 1986.

RARE EARTHS

Local area prospectors have become interested in the rare earth content of pegmatite deposits. As a result, a property has been staked for samarium in the northwestern part of the area, and further exploration is expected in 1986.

GOLD

Limited exploration for gold, mainly by local prospectors, continued in the Huntsville-Parry Sound area. Most of the work centres around the possible association of gold with pyrite and chalcopyrite mineralization.

QUARTZ

A zoned pegmatite deposit in Murchison Township underwent minor development work in 1985.

STONE

Some interest for building stone was shown in 1985. Inquiries concentrated on potential sources of red or black "granite" suitable for interior or exterior facing. There was also some interest expressed in flagstone, as there are already several producing quarries within the area.

MINING ACTIVITY

Numerous quarries, most notably the Mill Lake Quarry at Parry Sound, produced flagstone for use primarily as a building stone. The Mill Lake Quarry produces several products, including a very attractive one-half inch flagstone, that is easily installed on interior walls.

An amazonite quarry in Chapman Township, northeast of Magnetawan, was opened up as a commercial mineral collecting site. There is also a substantial deposit of garnets on the property which the owner hopes to develop in 1986 as a mineral collecting site. Tourists are transported to the quarry in a horse and wagon.

MINERAL EDUCATION PROGRAM

During the year, regional geological staff visited four Provincial Parks: Killbear (2 visits), Grundy (2 visits), Arrowhead, and Oastler Lake, to give an introductory talk on minerals and geology, followed by a field trip within the park. Staff also visited two junior ranger

camps in the Bracebridge and Parry Sound areas for a day-long session on minerals.

RECOMMENDATIONS

Recommendations for exploration are difficult to make when the geological data base is poor to inadequate. With significant expenditures planned through the Federal-Provincial Minerals Agreement, an improvement in the data base is expected.

Graphite is one commodity that deserves a look because of improved market conditions and a better understanding of the mineral. Although two properties are presently being subjected to substantial work programs, numerous occurrences exist throughout the area, for which little data is known. Reconnaissance and detailed mapping from a structural point of view may be the best means of detecting additional deposits.

Pegmatites should be examined for their rare earth potential, particularly since Precambrian bedrock mapping will be carried out in the area northeast of Parry Sound, under the Federal-Provincial Minerals Agreement.

The marbles northeast of Parry Sound should be examined for refractory minerals.

The potential for "stone" is considered as "unknown to good". In the joint project with the Eastern Region, several interesting areas of red "meta-granite" and dark green "meta-gabbro", requiring a more detailed assessment, were detected. Flagstone is an active local industry which has potential for expansion outside the area.

The potential for mineral collecting, although unknown at this time, will be better evaluated when additional bedrock mapping of the Precambrian is done.

12. Bancroft Resident Geologist Area, Algonquin Region

Hans D. Meyn

Resident Geologist, Ontario Ministry of Northern Development and Mines, Bancroft

INTRODUCTION

The Bancroft Resident Geologist Office is responsible for the Minden, Bancroft, and Pembroke Districts, which are part of the Algonquin Region of the Ontario Ministry of Northern Development and Mines. The other three districts of the Algonquin Region, Parry Sound, Bracebridge, and Algonquin Park, are the responsibility of D.J. Villard, Resident Geologist, Huntsville.

During 1985, the boundaries of the Resident Geologist, Huntsville, and the Resident Geologist, Bancroft, were realigned on the basis of geology, rather than district boundaries. Thus D.J. Villard is responsible for the Central Gneiss Belt (*see* Report of the Huntsville Resident Geologist, this volume), and H.D. Meyn is responsible for the Central Metasedimentary Belt (Figure 12.1). Since the new boundary was established during the course of the year, some of the information in the tables does not yet accurately reflect the boundary change. Some duplication between this report and that of D.J. Villard will be noted, and some information will be plotted outside the new Resident Geologist's area.

The Bancroft office is staffed by Hans D. Meyn, and Karen Fell, secretary. The drill core library was administered by Harald Wolf, who resigned in September. That position has subsequently been vacant.

RESIDENT GEOLOGIST'S ACTIVITIES

The Resident Geologist devoted some time to familiarization with the geology and mineral deposits of the area. Known, currently inactive, mineral occurrences were visited, and new properties undergoing exploration were visited in the company of the owner or operator. The operating mines were also visited.

The Resident Geologist also participated in several field trips, most of them given by persons doing geological work in the area, either for the provincial or federal governments, or a university.

Mineral collecting (rockhounding) is an important part of the economy of the Bancroft area and the Resident Geologist was involved with the Chamber of Commerce in supporting mineral collecting in the Bancroft area.

As part of that effort, the Ontario Ministry of Natural Resources, Algonquin Region, this year again sponsored a booth at the Bancroft Gemboree and the Wilberforce Rockhound Fair, at which mineral and geologically oriented publications issued by the Ministry were on sale. As in previous years, the Ministry of Natural Resources sponsored D.H. Gorman, Professor of Mineralogy, University of Toronto, at these two events to identify rocks and minerals for the rockhounds.

In addition, the Bancroft office produced an inventory of the known mineral collecting sites in the Algonquin Region. This is a compilation of sites taken from all the guidebooks available to us. This inventory is available to the public for inspection at the libraries of the Resident Geologists in Bancroft and Huntsville, and the Mines Library, Ontario Geological Survey, Toronto. As a follow-up to this project, accurate locations for these sites are currently being plotted, and the status of the land with respect to Crown ownership is being established.

Under a Special Employment Project, two geologists were hired to map the York River area in Dungannon Township. This area is one of the more popular mineral collecting areas, with five sites reasonably close to each other and a good variety of minerals available. The intent of the mapping was to better understand the geological setting and to gain some appreciation of the size of the resource available.

DRILL CORE LIBRARY

The Drill Core Library in Bancroft was opened in the spring of 1984. Until September 1985, under the supervision of Harald Wolf, about 42 000 m of core were collected and filed in the new facility. Another 10 000 m are stored outside awaiting processing. The core now in the library represents 542 drillholes from 23 properties in 16 townships representing copper-nickel-cobalt, iron, zinc, uranium, graphite, nepheline syenite, and quartz mineralization.

Data pertaining to the drill core is stored on a microcomputer. This information includes the company name, company drillhole number, year of completion, township, drillhole length, amount of core stored, and whether assays, chemical analyses, thin sections, or polished sections are available. A number of search programs have been written to manipulate the data, thus making it possible to list all drillholes from a specific area by a certain company name or other criteria.

As the drill core library is situated in the Ontario Ministry of Natural Resources compound at Bancroft, about 100 m from the Resident Geologist office, complete assessment files are kept in the library building. Eventually the documents in the assessment files will be marked to indicate what core or samples are available in the drill core library and how they relate to the assessment files.

As a result of the resignation of the drill core librarian in September, access to the drill core library is by appointment only, through the Resident Geologist, until April or May, 1986.

the former's absence; J. Etches is currently Mineral Resource Assistant. A. Moore and J. Switzer worked in the Lapidary Room, and J. Hallworth worked on the Peatlands inventory of the Frost Centre.

About 5000 visitors participated in tours and lectures in the mineral resources field. The staff of the Frost Centre gave lectures at two Junior Ranger camps. A reconnaissance peatlands/wetlands inventory of the Frost Centre was completed and submitted to the Ontario Geological Survey for comment. Thirty new sites were evaluated for the lapidary stone inventory, and several samples for the regional building stone project were prepared in the lapidary facility.

ALGONQUIN AND EASTERN REGIONS

C.P. Verschuren (Verschuren 1985), working out of the Tweed office, undertook a survey for building stone potential of the Algonquin and Eastern Regions of the Ministry of Natural Resources.

ONTARIO GEOLOGICAL SURVEY

Maps and reports pertaining to the Bancroft Resident Geologist area and issued by the Ontario Geological Survey are shown in Figure 12.1 and listed in Table 12.1. Additional references to new information of geological interest in the general area are included in the list of selected references. Also shown in Figure 12.1 is the location of the 1985 field work done by the Ontario Geological Survey.

A field party under the leadership of R.M. Easton continued detailed mapping (1:15 840 or 1 inch to 1/4 mile) in the Minden area with the Lochlin Area sheet (Easton 1985). As part of that study, M. Zeeman investigated the building stone potential of certain rocks in that map area (Easton and Zeeman 1985).

J.S. Springer of the Mineral Deposits Section continued her studies of the metallic and industrial minerals in the Grenville Province (Springer 1985).

P.J. Barnett of the Engineering and Terrain Geology Section carried out additional field investigations in the Golden Lake and Pembroke areas in preparation for preliminary Quaternary geology maps, Barnett (1985).

The aggregate assessment group continued field work in Harvey and Belmont Townships in preparation for Aggregate Resource Inventory Papers for these two townships (Ontario Geological Survey 1984a).

GEOLOGICAL SURVEY OF CANADA

W.W. Shilts and associates are continuing their study of the Quaternary deposits of Ontario with respect to their acid rain buffering capacity, their economic potential, suitable prospecting methods therein, and their geological history. As well, a study of glacial erosion of the Canadian Shield is being conducted by C.A. Kaszycki.

A.P. Stenson is continuing her study of mineral collecting in Canada. A new guidebook for the Bancroft area is expected to be released in 1986.

A. Davidson and associates are continuing with the regional synthesis of the Grenville Province in Ontario and Quebec.

S. Hanmer is continuing his studies of structural boundaries in the Grenville Province of Ontario and Quebec.

ROYAL ONTARIO MUSEUM

S.B. Lumbers continued his studies of the northwestern boundary of the Central Metasedimentary Belt in the area east of Haliburton.

Malcolm Back finished a B.Sc. thesis at the University of Toronto on the mineralogy of selected localities in Monmouth and Glamorgan Townships.

EXPLORATION ACTIVITY DURING THE YEAR.

TABLE 12.2

Number on Figure	Individual or Company	Activity
1	Bailey, R.M.	Claim Staking (1), Lutterworth Twp.
2	Belanger, B.P.	Claim Staking (3), Maria Twp.
3	Byer, J.L.	Claim Staking (2), Drilling, Burleigh Twp.

17	Richter, D.A.	Claim Staking (3), Cavendish Twp.
18	Schroetter, R.	Claim Staking (1), Dungannon Twp.

UNIVERSITIES

R. Thivierge, University of Ottawa, is completing an M.Sc. thesis on the Centreville-Combermere area.

L. Heaman, McMaster University, Hamilton, is in the process of writing up his Ph.D. thesis on isotopes and trace elements in the Chandos Township area.

Steve Dunn, University of Wisconsin, is continuing a Ph.D. study of stable isotopes of some of the gabbroic bodies of the Bancroft area.

D.M. Burton, University of New Brunswick, completed an M.Sc. thesis on the geology of the Cam uranium deposit, Cardiff Township (Burton 1985).

R.L. Bedell, University of Toronto, completed an M.Sc. thesis entitled "Madawaska Mines, Bancroft, Ontario: Deformation of the Faraday Metagabbro Complex and its Influence on Uraniferous Pegmatite Emplacement and Ore Deposition" (Bedell 1985).

Martin Van Kranendonk, University of Toronto, is studying several anorthosite bodies in the Muskoka District as part of an M.Sc. thesis (Van Kranendonk 1985).

Several Canadian and American universities have annual field trips to the Bancroft area. These are generally at the undergraduate level. The University of Windsor holds their annual field camp just south of Bancroft, and the University of Ottawa holds theirs in the Calabogie area.

EXPLORATION ACTIVITY

The location of properties which were staked and those on which exploration work is known to have been done in 1985 are listed in Table 12.2 and shown in Figure 12.1, keyed to Table 12.2. Assessment work reports received in this office are listed in Table 12.3.

The area saw continuing activity for building stone with staking in Dungannon, Faraday, Cavendish, and Cashel Townships.

Some work was done in Mayo, Cashel, Burleigh, and Griffith Townships on marble deposits for use as either building stone or mineral filler.

Princeton Resources Corporation continued work in Maria Township, where additional staking was done for graphite. Beneficiation studies are underway and a test mill is contemplated.

Sulpetro Minerals Limited continued work at the Renprior/Cadieux zinc property in Admaston Township. Some diamond drilling was done this year.

R.J. Crawford is continuing base-metal exploration on his claims in southwestern Lyndoch Township. Considerable vermiculite was discovered during the course of this work.

Jayfran Enterprises Limited expanded their holdings of nepheline syenite in Dungannon Township and did mapping and sampling.

R.N. Cloughley expanded his holdings in Dalton Township where he is doing precious metal exploration.

R.L.V. Ekstrom staked the Spain Mine, a former molybdenum producer, in Griffith Township.

MINING ACTIVITY

The locations of the operating mines and quarries are shown in Figure 12.1.

During late 1984, Falconbridge Limited bought the remaining publicly held shares of Indusmin Limited and that company became a division of Falconbridge Limited. During 1985, Falconbridge Limited also bought the nepheline syenite operations of International Minerals & Chemical Corporation (Canada) Limited at Blue Mountain. All the nepheline syenite quarries and plants in Methuen Township are now being operated by Indusmin Division of Falconbridge Limited. Both plants produce a wide range of products for the glass, ceramic, fibreglass, and filler industries.

Chromasco Limited, a division of Timminco Limited, near Haley Station, Ross Township, produces in its reduction plant magnesium metal from dolomite mined in two pits on the property. High purity calcium and strontium metal is also produced on demand from material purchased off site. The company operated at capacity during 1985.

Crushed stone for aggregate is produced from two quarries in McNab Township. Crushed stone for aggregate, tile beds, and gabions, as well as flagstone, and edging stone is produced from four quar-

ries in Harvey Township. Flagstone is also produced from the MacDonald Quarry in Lutterworth Township.

White dolomite is produced at the quarry of Bolender's Limited, Guilford Township, for poultry grit, golf sand, exposed concrete facing, and white bricks and mortar.

Rose quartz chips are produced on demand from the West Quarry of Wal-Gem Lapidary in Lyndoch Township.

Mineral specimens are produced from both the East and West Quarries of Wal-Gem Lapidary. Sodalite for the lapidary trade and mineral collectors is produced on a demand basis at the Princess Sodalite Mine, Dungannon Township, just east of Bancroft.

RECOMMENDATIONS

The Bancroft area is close to the markets of Ontario, Quebec, and the northeastern United States. Adequate road, rail, and water transportation routes exist, good access is normal, an adequate labour pool, and other features of a stable, well developed infrastructure are in place. A deposit of adequate size and consistent grade should be able to compete in these markets.

Potential exists in the area for graphite, talc, high purity calcium, high purity silica, and building stone. Mica as filler is still somewhat of a new industry, but the potential market is seen to be excellent. North American markets also exist for coarse "book" mica (muscovite or phlogopite) which, in the past, has been produced locally from pegmatite deposits.

In Ontario, Quebec, and New York State, several mines have operated, or are still operating, based on sphalerite associated with carbonate metasediments. Potential for such deposits exists in much of Eastern Ontario.

The Minden-Bancroft-Pembroke area has numerous pegmatite occurrences and, in the past, several mines were developed on these pegmatites. Pegmatites containing mica, silica, calcite, potassic feldspar, radioactive minerals, and rare earth minerals are known. Based on several coproducts, it may be possible to bring one, or several adjacent ones, into production.

13. Eastern Resident Geologist Area, Eastern Region

P.W. Kingston[1] and V.C. Papertzian[2]

[1]Resident Geologist, Ontario Ministry of Natural Resources, Tweed

[2]Project Geologist, Ontario Ministry of Natural Resources, Tweed

INTRODUCTION

During 1985, exploration for industrial minerals and precious metals was the main activity by mining companies, prospectors, staff of the Resident Geologist's office, and of the Ontario Geological Survey (OGS). The emphasis was on gold, building stone (granite and marble), talc, calcium carbonate, graphite, and vermiculite.

RESIDENT GEOLOGIST'S ACTIVITIES

The office of the Resident Geologist for the Eastern Region is located in Tweed and is staffed by P.W. Kingston, Resident Geologist; L.G.D. Thompson, Geophysicist; S. van Haaften, Core Library Geologist; and three full-time contract geological staff. The contract staff consists of V.C. Papertzian, C.P. Verschuren, and D.A. Williams.

W.M. Kelly was the Assistant Core Library Geologist up until October 18, 1985, at which time he left the Ontario Government.

The office of the Regional Mineral Resources Coordinator is located in Kemptville and is staffed by T.W. Fletcher, Regional Mineral Resources Coordinator; Y.F. Young, Mineral Resources Specialist; and two contract and part-time staff, D. Brand and K. Klassen. Five Experience '85 students were hired to work on various geological projects in the region.

Most geological and geophysical activities are managed by the Resident Geologist in Tweed. All geotechnical, aggregate assessment, mineral education, and Provincial Parks projects are managed by the Regional Mineral Resources Coordinator in Kemptville.

As in previous years, much of the Resident Geologist's time was involved in providing a consultive technical service to companies and individuals engaged in mineral exploration and mining development in the Eastern Region. Selected mineral properties in the region were visited during the year either because of their importance to Ministry programs, or because of interest in, or work by, mining and exploration companies. Emphasis was placed on examining properties currently under development, especially those involving industrial minerals. Other activities included conducting and attending geological field trips and tours.

During 1985, P.W. Kingston and W.F. Caley (Associate Professor, Metallurgical Engineering, Technical University of Nova Scotia, Halifax), carried out an investigation of the historical and metallurgical aspects of small scale lead smelting practice in Eastern Ontario during the first decade of this century. In particular, refractory samples from the Ontario Mining and Smelting Company of the Hollandia Lead Mine near Bannockburn, in the County of Hastings, were collected and examined for alteration in mineral composition as a result of the smelting operation. Using electron microprobe and optical microscope techniques, an estimate of operating conditions such as flux usage and smelting temperature was determined.

The study showed that while the chemistry of the ore was not compatible with the type of refractory used, and while the matte permeated one third to one half of the brick, the lining still survived this particular operation. This was probably a result of a relatively low residence time of the melt in the shaft furnace, combined with the small number of heats to which the refractory was exposed.

The smelter at Hollandia was most likely abandoned because it did not suit the plans of the Stanley Smelting Company when it took over from the Ontario Smelting and Refining Company in 1905. The Stanley Smelting Company wanted a much larger capacity smelter located at the rail junction and capable of drawing on several mines for ore. In addition, the new smelter superintendent was more knowledgeable in lead smelting practice and the use of fluxing agents such as iron oxide and silica, and undoubtedly recognized the shortcomings of the Hollandia works.

A paper on this subject was presented by P.W. Kingston at the Joint Annual Meeting of the Geological Association of Canada and the Mineralogical Association of Canada in Fredericton, New Brunswick, in May 1985, as part of a special session on Applied Mineralogy in Science and Technology (Caley and Kingston 1985). The paper is currently in press in the Journal of the Mineralogical Association of Canada: Canadian Mineralogist (Caley and Kingston, in press).

In January of 1985, a special employment program (Mining Sector Work Program) was set up with the city of Cornwall acting as project sponsor. This project employed six people to carry out an exhaustive literature survey and to inventory all building stone occurrences in eastern Ontario. The program finished March 31, 1985, resulting in the publication of Open File Report 5556, Building Stones of Eastern Ontario, by C.P. Verschuren, S. van Haaften, and P.W. Kingston (1985). In addition, two Section 38 work programs employing ten people were initiated on September 3, 1985, sponsored by the Crowe Valley Conservation Authority. One consisted of collecting 300- to 500-pound test blocks of both granite and marble from potential building stone sites. A portable gasoline-powered drill and plugs and feathers were used to collect test blocks which were subsequently cut and polished into 1 inch thick, 12-inch square slabs.

The second project has upgraded, reorganized, and enabled computer access to the Eastern Region mineral deposits files, and was designed to be compatible with the mineral deposits systems at the Geoscience Data Centre, Ontario Geological Survey and at the Algonquin Region, Ministry of Natural Resources (MNR). The project employed 6 persons for 17 weeks.

The paper files and the computer databases are housed at the diamond-drill core library at Tweed and are available for public access.

FIELD TRIPS

In mid-January in Ottawa, the Current Activities Forum of the Geological Survey of Canada was attended by P.W. Kingston, V.C. Papertzian, C.P. Verschuren, and L.G.D. Thompson.

A tour of the new Karnuk Marble plant in Cornwall, Ontario, was arranged by P.W. Kingston, V.C. Papertzian, and C.P. Verschuren.

A two-day field trip was organized by the Southwestern Region Ministry of Natural Resources to look at a number of building stone quarries in the Paleozoic dolostones of the Bruce Peninsula. Arriscraft Corporation of Cambridge, Ontario was visited on the first day of the tour, while three quarries were visited on the second day in the vicinity of Wiarton, Ontario. P.W. Kingston, V.C. Papertzian, and C.P. Verschuren attended this field trip.

A four-day field trip organized by the Industrial Minerals Section of the OGS and Algonquin Region toured eastern Ontario and part of Quebec at the end of May 1985. Two days were spent looking at building stone properties in eastern Ontario. A few people continued on to Quebec City and toured a number of granite-finishing plants, as well as a number of granite quarries.

A four-day field trip to Vermont occurred on June 24 to 27, 1985. Both Rock of Ages and Vermont Marble finishing plants and quarries were visited.

In late October, a four-day building stone program was jointly hosted by OGS and Eastern Region. One and one-half days of lectures by Asher Shadman, a world-renowned stone consultant from Israel, were combined with a two-day field trip around both the Kingston and Cornwall areas. The field trip was organized and conducted by V.C. Papertzian and P.W. Kingston, who also edited the field trip guide (Papertzian and Kingston 1985). All geological staff from the Tweed office attended this field trip.

EXPLORATION ACTIVITY

In 1985, approximately 258 new claims were recorded in the Eastern Region, a decrease of 128 claims over 1984. This decrease is partly the result of gold properties being retained by companies for further exploration work (Table 13.1).

Figure 13.1 shows the area of claim staking activity and assessment work filed during the year. Claim staking activity decreased by 33%, while claim cancellations decreased to 225 compared to 372 last year in Eastern Region (Figure 13.2). Figure 13.3 shows the location of active mining properties as well as operating mills and processing plants.

Since much of the exploration work undertaken in Eastern Region is on private land, companies are not obligated to report activities. However, many have kept the Ministry of Natural Resources informed of their activities, and in many cases, have voluntarily supplied information on a confidential basis. It is, therefore, not possible to report on all of the exploration activity in the Eastern Region.

E B Canada Resources Limited (acquired by Imperial Metals Corporation) of Vancouver has not carried out any further work at the Addington Mine Property (Golden Fleece Deposit) since the winter of 1983. A total of 27 000 feet (8230 m) of diamond drilling has been completed on the property and has been donated to the Tweed Drill Core Library. To date the results have been encouraging.

No further exploration work has been carried out on the Ore Chimney Gold Mine Property since it was dewatered to the 150-foot level a couple of summers ago. A number of mining concerns have examined the property, but as yet no further work has been carried out.

Steep Rock Resources Incorporated explored for high-grade calcite (marble), and for other industrial minerals. The company continues to make heavy plant investments in Eastern Ontario for industrial mineral processing.

Canada Talc Industries Limited continues a modest exploration effort, mostly on their Madoc Property. Mine ore reserves have been substantially increased over the last few years and efforts to develop at least one new property are under way.

There has been considerable interest in graphite in the last year with active exploration on the more promising properties. The Cornell Property has changed hands recently and an exploration program is being planned by the new owners.

The Omya Incorporated flake muscovite mica deposit near Kaladar was re-evaluated this year, and several companies have examined the property. The mica appears to have good potential as a functional filler in the plastics industry.

Local prospectors R. Young and J. Byer have been actively exploring sillimanite, talc, and high-calcium marble properties.

Twin Buttes Exploration Incorporated optioned a talc property in Madoc Township and carried out a geological mapping program this summer. Several thousand feet of diamond drilling have indicated a possible 2-million ton talc deposit to a depth of 30 m. The company is now preparing a market study based on talc product samples.

The following description of the Mono Gold Mines Incorporated Property at Bannockburn was taken from the George Cross Newsletter, dated October 8, 1985, Volume 194 (1985):

> The drilling has defined the northern and eastern boundaries of the visible gold mineralization (seen in drill cores), which occurs in 4 or more vein structures for a total vein length of 1260 feet. The veins vary in width between 0.1 feet and 3.0 feet, strike NW and dip NE at -45 to -65 degrees. The veins appear to be related to a transverse ENE striking flexure-fault that dips northward at 60 degrees. The best gold values have been obtained within 300 feet to the north of this structure and also to the south of it.

ASSESSMENT WORK AND OTHER INFORMATION RECEIVED.

+ Claim staking activity

Boundary of Resident Geologist's Area

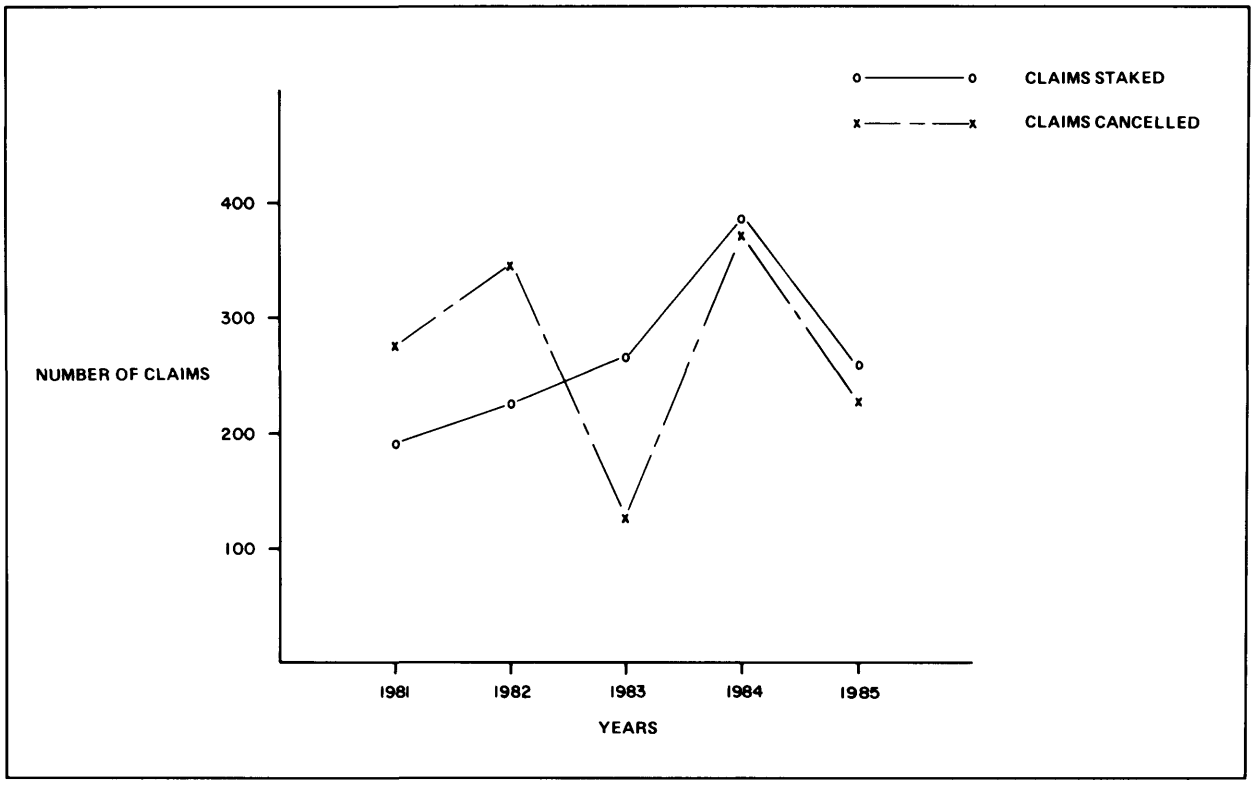

Figure 13.2 . Claim staking and cancellation activity in Eastern Ontario

Proven ore reserves require underground confirmation in this type of deposit, but, based on 31 diamond drill intercepts that have been diluted to 5.0 feet true widths at vertical depths between 5 and 240 feet, the drill indicated tonnage is about 90 000 tons grading 0.327 ounce of gold per ton. The drilling also indicates that additional reserves may be present in high grade linear shoots along the flexure fault, but, these will require underground sampling for confirmation. Further reserves could be established SW of the flexure fault, where additional drilling has yet to be conducted. Also, the depth of gold mineralization remains to be established.

Elsewhere on the property, ongoing geochemical soil surveys have identified 3 linear anomalies. One, within 600 feet of the old Bannockburn gold mine, is 1200 feet long and open at both ends.

Ram Petroleums Limited hold mining leases on a large talc-tremolite body and operate a mill near Robertsville. The company, through Commercial Industrial Minerals Limited, a subsidiary, are strongly promoting the use of the tremolite product (called clarendite by the Company) as an asbestos-substitute binder in asphalt paving. The company has spent $120 000 modifying the grinding circuits and installing a dryer. The following is quoted from The Northern Miner (December 9, 1985).

Based on diamond drilling, the deposit contains 2 862 000 proven tons of ore to a depth of 250 ft. Reserves are 2 200 000 tons of clarendite, 390 000 tons of talc and 143 000 tons of phlogopite mica.

The deposit is zoned and mica and talc zones can be mined selectively by open pit. Test results show that the phlogopite can be separated from clarendite by a dry screening process. The orebody is open along strike and to depth. Mining is by open pit. The dry milling method uses a Hardinge autogenous mill.

Tests are currently under way to evaluate the potential of clarendite in a number of other applications. The most promising use of clarendite is as concrete reinforcing additive.

The company has also done property evaluations and mill tests on sillimanite, muscovite mica, and talc.

Karnuk Marble Industries Incorporated of Cornwall has recently installed a very large Breton gang saw to cut 20-tonne granite blocks into slabs to make exterior cladding for building. The company is producing marble tiles from imported stone and is actively exploring several Ontario sources.

MINING ACTIVITY

Canada Talc Industries Limited continued to operate their underground talc mine and adjoining open pits (dark talc, and talciferous dolomite) at Madoc, and their processing plants at Madoc and Marmora. Production is up to approximately 50 000 tons per year (up from 20 000 tons per year several years ago). About 70% of ore mined is high brightness talc and is about 30% is dark talc (brightness about 80). The high brightness talc is ground to make a number of products ranging from 50 to 10 microns in size, including filler for plastics, paint, paper, rubber, tile, and carpets. The dark talc is used in the manufacture of automotive body patch compounds. In addition, several thousand tons annually of talciferous dolomite are ground and sold for specialized filler markets. The company is agressively pursuing expansion plans in both high-brightness and dark talc markets, and is planning plant improvements in the near future.

Steep Rock Resources Incorporated operate an open pit calcite mine near Tatlock and a plant at Perth. Quarrying is done by contract in the summer months, and in excess of 100 000 tonnes is trucked to the plant which operates 12 months of the year employing 56 men. Products include finely ground calcite for filling and coating paper, plastics, rubber, stucco, and floor tile. Other products include crushed and sized calcite for golf traps, agricultural lime, landscape stone, decorative stone, and precast concrete. The finer grinds are shipped by tank truck or semibulk bags, while the coarser sizes are mainly bagged for shipment.

In late 1985, construction of an ultrafine plant to grind and float micron-size calcite was commenced. This plant is a joint venture of Steep Rock Resource Limited and Georgia Kaolin Limited (Canadian Division) and will produce a premium product destined mainly for the alkali paper market in the United States and Canada.

Fairmont Granite Limited-Battersea Quarry Planned production from the Battersea Quarry for 1985 was 20 000 cubic feet of granite. Some of this production was shipped to Vancouver, B.C., to be used in the Bank of British Columbia. The remainder was shipped to Japan, Vermont, and Quebec. The recovery at this quarry site is approximately 35% to 40%. The granite is uniformly pink in colour, and grain size varies from medium to coarse. Limited jointing occurs in a regular pattern. Some chloritic seams containing scattered pyrite are seen in some of the waste blocks in the grout pile. Discontinous quartz veining also occurs in this deposit. Six workers are employed from early Spring to late Fall.

Fairmont Granite Limited is a wholly-owned subsidiary of Rock of Ages Corporation of Barre, Vermont.

Sloan Quarry: Five small quarry openings are located on the Sloan farm on lot 11, concession 6, Storrington Township, Frontenac County. One of the quarries is operated by Rideauview Contractors Limited, employing 11 men. The face of this quarry is approximately 15 feet to 20 feet high. The stone is a medium- to thin-bedded buff and salmon pink to red Potsdam sandstone. It has been known as "Kingston Hue".

This stone is marketed for decorative use (e.g. fireplaces, feature walls) and is sold by the pallet load from the quarry site. Some of the waste stone was sold this year for use in the manufacture of fibreglass.

Stoklosar Marble Quarries Limited operated approximately nine marble quarries in the vicinity of Madoc during 1985, and operated two crushing, screening, and bagging plants in and near Madoc. In 1982, Stoklosar Marble Quarries Limited was formed by the amalgamation of Grenville Aggregate Specialties Limited and Stoklosar Marble Quarries (1969) Limited. The company produced 4038 tons of crushed marble, an increase over the 1984 production. The marble is crushed to produce a wide range of products. Terrazzo chips make up 46% of the production, while precast panels account for 30%. Stucco, decorative stone, and dust comprises 15%. Nine percent of the total production is shipped to the United States.

The following production figures are broken down by colour and are from both plants. A quarry north of Eldorado produced 1068 tons this year of medium-grained buff coloured marble, the most popular colour shipped.

A quarry north of Malone on the Moira River produced 906 tons of white marble. During the crushing process, 413 tons of white dust were collected and sold as additive for cement in the construction of swimming pools. The buff and white coloured products account for one half of the total production figure.

Other colours produced are: light buff (540 tons); pink (369 tons); light green (389 tons); chocolate red (257 tons); blue (97 tons); and black (55 tons).

The terrazzo chip product is marketed through Domus Engineering Limited of Toronto and is used in construction projects throughout eastern North America.

A.L. Blair Construction Limited produced 15 000 to 20 000 tonnes of agricultural lime from their St. Albert quarry in Finch Township near Cornwall, Ontario. The agriculture lime is crushed by hammer mill to pass a 50 mesh screen.

Rideau Granite Limited operated two granite quarries at Straw Hill near Seeleys Bay under the management of R. Cloutier. About 200 tons of red granite blocks were quarried for architectural and monument purposes. Mr. Cloutier also operates a small granite finishing plant in Brockville.

Cornwall Gravel Company Limited has stripped an area northeast and adjacent to their main limestone aggregate quarry two miles north of Cornwall, and produced approximately one hundred 8- to 12-ton building stone blocks from the topmost of two thick (1.2 to 1.5 m) layers of Lower Bobcaygeon black limestone. When polished, the limestone is an attrac-

tive black and contains small irregular patches of white to grey limestone. Karnuk Marble Industries Incorporated have purchased a number of blocks to fill several orders for 12-inch by 12-inch tiles.

U. Kretchmar (of Severn Bridge) and Aur Resources Incorporated (of Toronto) are re-evaluating the Tweed marble quarry located about 4 miles north of Tweed. This formerly producing quarry operated in the late 1960s and provided commercial architectural slabs for numerous building projects, including the Canada Trust Building in Toronto, the Provincial Museum and Archives Building in Edmonton, Alberta, and the St. Lawrence Centre in Toronto. The marble was cut and polished in four colours: Tweed White, Tweed Vert, Tweed Pearl, and Tweed Variegated.

ONTARIO GEOLOGICAL SURVEY ACTIVITIES

The Precambrian Geology Section released the preliminary geology map for the Mellon Lake area by Bright (1985). This map covers the western portion of the Claire River Syncline, an area which is being actively explored by several companies for flake muscovite mica.

The Engineering and Terrain Geology Section of the Ontario Geological Survey was active in Eastern Region during the 1985 season (Figure 13.4).

Paleozoic geology maps of part of the Ottawa-St. Lawrence Lowland were published in April 1985. The map areas consist of the following: Russell-Thurso (Williams, Rae, and Wolf 1985a); Hawkesbury-Lachute (Williams, Rae, and Wolf 1985b); Alexandria-Vaudreuil (Williams, Rae, and Wolf 1985c); Cornwall-Huntingdon (Williams, Wolf and Carson 1985a); Winchester (Williams, Wolf, and Carson 1985b); and Morrisburg (Wiliams, Wolf, and Carson 1985c). A final report on the Paleozoic geology of the Ottawa-St. Lawrence Lowland is in preparation by D.A. Williams.

Another six Paleozoic geology maps were published in early December, 1985. The map areas consist of the following: Pembroke Area (Russell and Williams 1985a); Fort Coulonge Area (Russell and Williams 1985b); Golden Lake Area (Russell and Williams 1985c); Cobden Area (Russell and Williams 1985d); Brudenell Area (Russell and Williams 1985e) and Renfrew Area (Russell and Williams 1985f).

The Mineral Deposits Section carried out several programs in eastern Ontario, one of which (vermiculite) was a joint project with Eastern Region staff (MacKinnon *et al.* 1985a, 1985b, 1985c, in press). Malczak *et al.* (1985) completed an open file report on base metal, molybdenum, and precious metals in the Madoc-Sharbot Lake area. Malczak (1985) completed a map to accompany this report that was based on the recently completed geological compilation map by Kingston, Papertzian, and Williams (1985).

An open file report on the geology of selected gold occurrences in Anglesea, Barrie, and Clarendon Townships was written by Barron (1985). A study on talc in the Tudor Formation in southeastern Ontario was released as Open File Report 5530, by Dillon and Barron (1985), and an Open File Report on Gold-Quartz-Arsenopyrite veins geologically related to the base of the Flinton Group in Kaladar and Barrie Townships was completed by Dillon (1985).

M. Vos is studying the potential for ceramic raw materials in granites and anorthosites in the Westport Area. An interim report of his activities was published this year (Vos 1985). There appears to be some potential for producing potassium feldspar along with by-product quartz.

J. Springer is continuing to study the concentration of iron oxides and gold at the Paleozoic-Precambrian unconformity in the Madoc area (Springer 1985). The potential for developing small deposits of iron oxides pigments looks promising.

GEOLOGICAL MAPPING

GENERAL GEOLOGY

The Geology and Mineral Deposits Map of the Kingston Area, compilation sheet (NTS 31 C), was published as a preliminary map (P.2611, scale 1:125 000) in early 1985 (Kingston, Papertzian, and Williams 1985). This map synthesizes geological data from 53 published maps as well as information from assessment work files and the geological files of the Resident Geologist's office. The map also includes the location of, and references to, 1129 mineral deposits in the area and replaces Geological Circular 12, and Maps 2053 and 2054, by Hewitt (1964), now out of print.

VERMICULITE

A vermiculite mapping project sponsored by the Crowe Valley Conservation Authority began in late 1984 (Figure 13.4), and continued in 1985. The area in and around the Olympus vermiculite pit was mapped at a scale of 1:10 000 (Figure 13.5). A preliminary report on this project was published by MacKinnon *et al.* 1985b).

The rocks observed in the map area consist of three general groups, each having a significant role in the development of vermiculite, which is best seen in a mineralized zone on the Olympus Mines Limited Property, Lanark County. The groups include: the Grenville Supergroup Metasediments, Late Precambrian Intrusive rocks, and Paleozoic rocks. The host of the mineralized zone is pyroxenite, a remetamorphosed unit of the Grenville Supergroup. Late Precambrian syenitic and dioritic intrusions provided the source of hydrothermal solutions, rich in silica and magnesium, which altered the dolomitic marble to pyroxenite and converted phlogopite to vermiculite. The Paleozoic rocks are not important in the development of the mineralized zone, but are still an essential component. This thin unit probably preserved the vermiculite by capping the soft pyroxenite during the main phases of glaciation. The waning phase of glaciation subsequently scraped off the last remnants of the Paleozoic Nepean Formation, exposing the pyroxenite to surficial weathering.

A market exists for a favourably located Ontario (Perth) producer for vermiculite concentrates of approximately 27 000 to 32 000 tons per year and an additional 8000 tons per year for expanded vermiculite (Beauregard 1982). Current uses of vermiculite

include horticulture, light weight plasters, loosefill insulation, and insulatory light weight concrete. An important consideration to the continued development of vermiculite resources is continued research and development of new technology such as improved beneficiation methods and new applications. For example, research has extended the use of vermiculite into glass fibre papers and textiles which are heat and fire resistant products, previously requiring asbestos.

R. Collings and J.M. Lamothe, (CANMET) are conducting beneficiation tests on a 350-pound chip sample and on a split drill core sample obtained from the Olympus Mines Property during this project.

A problem of considerable importance to environmentalists and government agencies is the presence of asbestiform fibres in dust from vermiculite operations. E. Chatfield of the Canadian Research Foundation is testing vermiculite from the Olympus pit for the presence of asbestiform fibres. The absence of fibre is essential to the viability of deposits.

A poster display and formal presentation was given at the Ontario Geological Survey Geoscience Research Seminar in Toronto in early December 1985, by MacKinnon *et al.* (1985a, 1985c). Information on this project was also published in the 1985 Summary of Field Work (MacKinnon *et al.* 1985b). A detailed open file report by MacKinnon *et al.* is now in press.

BUILDING STONE

A joint building stone program between the Eastern and Algonquin Regions, Ministry of Natural Resources, commenced early in the spring of 1985. The area covered by this project is shown on Figure 13.4. This project is summarized by Verschuren (1985). The main purpose of this program was to obtain an overview of building stones in each of the respective regions. To date, approximately 90 properties or areas have been investigated. A two-page folio has been completed for each property and in a number of cases a detailed map was produced. A poster display entitled "Building Stones of Central and Southeastern Ontario" by Kingston, Verschuren, Papertzian, and Villard (1985), summarizing some of the more interesting occurrences, was presented at the Ontario Geological Research Seminar in December of 1985. An open file report was completed on the program at the end of December 1985, (Verschuren, Papertzian, Kingston, and Villard, in press).

GEOTECHNICAL ENGINEERING PROGRAM by K. Klassen and T. Fletcher

The study of earth slope failures along the Ottawa River and its tributaries in the United Counties of Prescott and Russell has continued in the 1985 field season. This program is jointly funded by the Ontario Ministry of Municipal Affairs and Housing and the Ontario Ministry of Natural Resources. The objective of this study is to establish construction setbacks for use in planning residential development.

The slopes have been surveyed to establish geometry, stratigraphy, and evidence of failure. Over one hundred field vane tests have been performed, and nine sites sampled for laboratory testing. An additional four sites will be tested this fall.

A field trip was conducted in the United Counties for geologists from several universities and the Canadian and Ontario Geological Surveys.

The Mississippi Conservation Authority has initiated a program to test the clay at four sites in the Mississippi area, with Ontario Ministry of Natural Resources involvement. Data from the program will be used to help establish construction setbacks in the Mississippi area.

The Regional Mines Coordinator and his staff have continued to promote public awareness of landslides and landslide hazard lands and to provide consultations for specific sites and liaison and planning input to municipalities and conservation authorities.

AGGREGATE RESOURCES by Andrew Young

Drift thickness mapping of the Paleozoic bedrock continued this year in the United Counties of Leeds and Grenville.

The mapping outlines areas of bedrock within 1.5 m (5 feet) of the surface, and classifies the rock according to its aggregate potential (e.g. asphalt, granular A, etc.)

The study involves the compilation of geological maps with airphoto interpretation, water well logs, Ministry of Transportation and Communication's data, and field inspections. The compiled depth information enables contours to be drawn delineating the bedrock within the specified depth.

DIAMOND DRILL CORE LIBRARY by S. van Haaften

Staffing

S. van Haaften is currently the acting Core Library Geologist. W.M. Kelly was the assistant core library geologist until October, 1985, and K. Klein and T. Mullings were summer assistants.

Services

The following resources and services are offered:

(a) drill core from southern Ontario;
(b) facilities for logging and splitting core;
(c) binocular and petrographic microscopes;
(d) rock cutting and polishing equipment;
(e) geological maps and reports for use in the core library;
(f) eastern Ontario mineral deposits and building stone database searches on a microcomputer;
(g) searches of the Ontario Mineral Deposits Inventory database; this OGS database is accessed over telephone lines by the core library microcomputer; and
(h) the assessment files, mineral deposit files, and old underground mine plans from the Resident Geologist's office are currently housed in the core library.

As of December 2, 1985, 48 816.6 m of core were catalogued, and approximately 10 000 m of

recently acquired core had yet to be entered into the catalog. Table 13.2 summarizes the library's catalogued holdings. During 1985, 19 195 m of core were catalogued.

Activities

As well as assisting clients and collecting, sorting, cataloguing, and documenting drill core, core library staff were involved in carrying out the following special projects:

(a) Computer-assisted compilation of building stone deposits in eastern Ontario. The compilation was carried out by a Section 38 program, and resulted in publication of the Open File Report "Building Stones of Eastern Ontario" (Verschuren, van Haaften, and Kingston 1985).

(b) Managing the compilation of a computerized mineral deposits inventory for eastern Ontario. This inventory is being compiled by a Section 38 program and is available for use at the core library.

(c) Participating in the MNR/OGS Perth Area Vermiculite project. W.M. Kelly assisted in the mapping, geophysics, and diamond drilling project.

(d) Minerals education. S. van Haaften gave geology talks at two elementary schools, led geology trips for teachers, junior rangers, and the Perth Naturalists' Club, and set up a publications and information booth at the Ottawa Lapsmith Club gem show.

SEISMIC SURVEYS by L.G.D. Thompson[1]

[1]Regional Geophysicist, Eastern Region, Ontario Ministry of Natural Resources, Tweed

In December 1984, at the Ontario Geoscience Seminar, the Regional Geophysicist presented a poster display on engineering seismic equipment and bedrock mapping.

In May 1985, at the request of B. Feenstra, Mineral Resources Geologist, Southwestern Region, the Regional Geophysicist visted several dimension stone quarries in the Bruce Peninsula. Consultation and advice were provided on the application of seismic methods to the assessment of dimension stone deposits.

In July 1985, an engineering seismic survey was conducted in the Russell-Lemieux area of Eastern Ontario to verify the location of faults identified on the Preliminary Paleozoic Geology Map P.2717 published in the spring of 1985 (Williams *et al.* 1985a). A detailed report on this seismic survey is published in

the Summary of Field Work, 1985, Ontario Geological Survey (Thompson 1985).

In September and October 1985, at the request of the Regional Geologist, Central Region and the District Geologist, Maple District, an engineering seismic survey was performed in the northwestern part of Brock Township. The purpose was to outline areas where Verulam limestone bedrock was very close to the surface. This information was needed to update the Ontario Geological Survey Aggregate Resources Inventory Paper No. 6 for Brock Township. This paper only outlined an area where the bedrock is covered by less than 8 m of overburden. Two seismic test lines and six actual survey lines were completed in an area where the seismic data showed bedrock to be from 1 to 10 m below the surface.

In October 1985, two seismic test lines were done on or near the property of John Bell near Clayton in Ramsay Township. The purpose was to trace an inferred fault in Grenville marble across the Bell property. Seismic results showed a slight (0.5 m) depression in the marble bedrock at the first site and a sharp 4 m drop in the marble bedrock at the second site.

In October 1985, engineering seismic tests were conducted at the Roblindale Quarry just south of Roblin in Camden Township in conjunction with a drilling program being done by Ontario Hydro in the quarry floor. The purpose was to try to map the Precambrian basement topography below the Gull River dolostone of the quarry floor. The seismic tests indicated that this is a difficult task. More test work is needed with particular attention being given to the type and location of the energy source.

In December 1985, Thompson (1985a) prepared a display and demonstration illustrating methods of seismic fault locating. Thompson (1985b) also published a paper on use of an engineering seismograph to locate buried faults.

GEOPHYSICAL STUDY OF FLUORITE DEPOSITS

INTRODUCTION

A geophysical investigation of the Moira fault and associated fluorite deposits in the Madoc area was initiated in the fall of 1984, with most of the reported work being done in 1985. The project supports the priority objective of the Ministry to stimulate the mining economy by the development of new mines. The Madoc area was a major producer of fluorite from 1905 to 1961 (Guillet 1964) when the availability of cheaper fluorite from Mexico forced the closure of the mines. Much of the area along the Moira fault, particularly to the northwest and southeast of previous mines, is difficult to explore except by geophysical methods. If viable fluorite deposits do exist in these areas and can be discovered, fluorite mining may once again be possible for the domestic market.

The only known reference to geophysical work done on the Moira fault and fluorite veins is in a report by Guillet entitled Fluorspar in Ontario (Guillet 1964). In 1944, A.A. Brant tried different geophysical methods along the Moira fault (Brant 1944). As reported by Guillet, self-potential and magnetic methods proved to be of little value. The resistivity method proved to be of most value. Resistivity measurements did not indicate the fluorite veins themselves, but did indicate the fault as a zone of higher conductivity usually coincident with a bedrock depression. Fluorite deposits were noted to be usually associated with the margins of the conducting zone.

Since direct detection of fluorite veins seems unlikely, this study has been divided into several phases as a logical approach to the application of geophysical methods. The first phase is to resolve whether or not the main fault break can be detected by geophysical methods at sites where the fault zone is known to exist. The second phase is to trace the main break into other areas of overburden where fluorite deposits may exist. The third phase is to find a correlation between fluorite veins and some characteristic feature of a geophysical anomaly associated with the fault. The fourth phase is to try to find new fluorite deposits associated with the main fault break. A further phase would be to extend the geophysical survey capability to find fluorite veins in parallel and *en echelon* fractures associated with the main fault.

Selection of suitable test sites where knowledge of the fault and fluorite veins was available was difficult. The old mine sites are now overgrown, with the surface and bedrock very disturbed, and are generally unsuitable for performing geophysical surveys. Therefore, attention was given to areas along the fault northwest and southeast of largest mines. Five sites were selected which are shown on Figure 13.6. At the Bailey mine, there is a large, fairly level, hay field northwest of the old mine workings. This offered the opportunity for geophysical tests over a known location of the Moira fault with a fluorite vein within the fault zone (although mined out). A similar but less favourable survey site is along the road between the Noyes and Johnston Mines. Another favourable site is on the Crookston road (concession 10 road) at lots 17 and 18, Huntingdon Township. Here the fault zone is a shallow depression about 14 m deep and 120 m wide, but the exact location of the main break is uncertain. A more favourable site is along concession 9 road, Hungerford Township just southeast of Buller Siding. According to Guillet, the fault crosses concession 9 road near the boundary line between lots 1 and 2, but the exact location is indefinite. A fifth site is further to the north along the road between lots 5 and 6, concession 3, Madoc Township at the O'Hara Mill Conservation Area. Here, a major fault has been mapped trending northwest as an extension of a fault line which includes the Moira fault (D.A. Williams, Geologist, Ontario Geological Survey, Tweed, personal communication, 1985).

Results presented in this report are for the first phase of detecting and locating the main fault break. The Electromagnetic (EM) and Seismic geophysical methods were employed because they appeared to have the best potential for fault locating. Results are given for the Bailey Mine site, Crookston road site, and Buller Siding site.

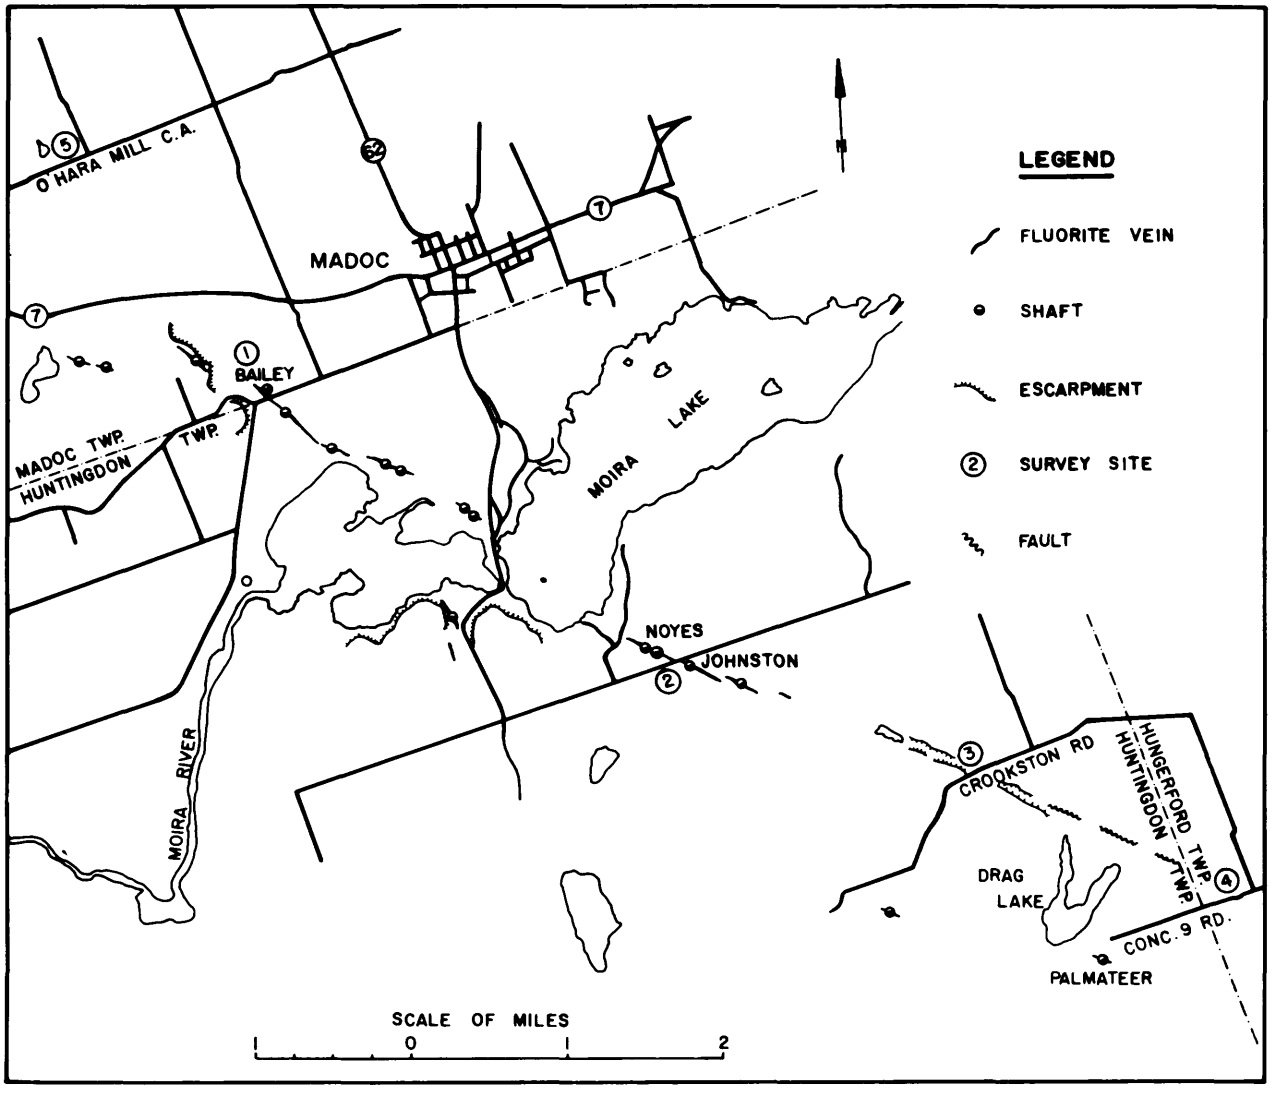

Figure 13.6 . Flourite occurrences in the Madoc Area (after Guillet 1964)

EM INSTRUMENT SYSTEM

A Geonics EM-31 Terrain Conductivity Meter was borrowed from the Quaternary Geology Office, Engineering and Terrain Geology Section, Ontario Geological Survey, in December 1984 and was used on this study until May 1985. The EM-31 is a resistivity-type instrument that measures conductivity directly in millimhos per metre (mmho/m). It has a depth penetration of about 6 m. The calibration of the instrument was checked in December 1984 to read 0.15 mmho/m over a bare granite gneiss outcrop and 1.4 mmho/m over bare Bobcaygeon (previously Upper Gull River) limestone on the floor of a quarry. These were considered correct and acceptable readings. The calibration of the instrument was again checked correct in May 1985 by Geonics staff at the calibration base at the Geonics plant in Mississauga.

SEISMIC INSTRUMENT SYSTEM

A single channel engineering seismic instrument system with modifications made by the Regional Geophysicist was used on this project. The system has been described in detail in previous reports (Kingston and Papertzian 1985; Thompson 1985). Basically it consists of a Nimbus ES-125 single channel engineering seismograph, a Nimbus ESR-100 strip chart recorder and Mark Products standard 50 Hz geophones. Modifications by the Regional Geophysicist include a 12-geophone cable with take-outs at 4 m intervals, a switch box for geophone selection and provision for two preamplifiers and bandpass filter circuits, a seismic energy source that fires 12 gauge slugs into the bottom of a 1 m deep hole and computer programs for seismic data processing.

GEOLOGICAL EXAMINATIONS

D.A. Williams, Paleozoic Geologist with the Ontario Geological Survey working out of the Tweed District Office, examined several limestone outcrop areas associated with the Moira fault. In particular, he identified the Paleozoic limestone formations and horizons in the test site areas of Crookston road and Buller Siding. This information helped to locate more precisely the main break of the Moira fault. In addition, the interpretation of the survey results was done in consultation with Mr. Williams.

PRELIMINARY EM SURVEYS

Some preliminary test lines were made with the EM-31 in December 1984 and early May 1985 at the Bailey Mine site, Crookston road site, O'Hara Mill site, and Noyes-Johnston site. Some test measurements were also made over fluorite vein extensions at several old mine sites and other known vein occurrences. The only significant conductivitiy anomaly was obtained at the Bailey Mine site. As a result, the Bailey Mine site was selected for more detailed investigation.

SURVEY RESULTS—BAILEY MINE SITE

Conductivity and seismic measurements were made and test holes drilled along a survey line 168 m long, and perpendicular to the strike of the fault and fluorite vein as expressed on the surface by a deep open cut. The survey line was northwest of the surface mine workings, in a hay field, but still over the underground workings 30 m down. The line started northeast of the mine workings and ran southwesterly to the property fence.

Figure 13.7 shows the plan view of the survey line in relation to the mine workings. Also shown are the locations of diamond-drill holes put down in the early 1940s, with overburden depths, the Precambrian-Paleozoic contact as determined from drill core logs, and the location of auger test holes drilled on this survey. Figure 13.7 also shows the EM profile along the survey line as well as a bedrock depth profile determined by seismics and auger test hole depths.

Conductivity measurements were made with the EM-31 every 4 m along the survey line. The resulting conductivity profile in Figure 13.7 shows a significant anomaly over the extension of the fault and fluorite vein, and another anomaly to the southeast near the fence. Based on bedrock depths determined by seismics and test hole drilling, the conductivity anomalies simply reflect the variation in thickness of the overburden.

Six seismic refraction lines were done at different overlapping sections of the survey line. Two lines (Baily-1 and 2) were shot in one direction only, but the others were shot in both forward and reverse directions. A summary of the seismic results is given in Table 13.3.

Twelve test holes were drilled with an auger bit at different locations along the survey line to check the bedrock depth (Figure 13.7). Five holes did not reach bedrock at a depth of 4.9 m which was the limit of available drill rods.

The bedrock depth profile in Figure 13.7 shows the bedrock is generally at a shallow depth of about 4 m or less. However, there is an abrupt, marked depression over 4.9 m in depth in the bedrock surface coincident with the extension of the fault zone from the surface mine workings. The Precambrian-Paleozoic contact is at the southwestern margin of the fault depression. The Paleozoic (Shadow Lake) limestone dips gently to the southwest, but rises abruptly near the boundary fence. The fluorite vein appears to be on the southwestern margin of the fault depression in the Precambrian wacke just northeast of the Paleozoic contact.

The depression could have been caused by surface mining of the vein and backfilling. However, previous mine descriptions (Guillet 1964) indicate that only an 80-foot open cut was surface mined, which is consistent with the still remaining open cut. Also, the sequence of overburden removed in the test holes over the depression was the same as that of the other test holes. There was no evidence of infilling with gravel or rubble. For these reasons, the depression is taken to be the fault zone.

SURVEY RESULTS—CROOKSTON ROAD SITE

Conductivity and seismic measurements were made across a fault depression about 14 m deep and 130 m wide that had a northwest-southeast trend. An approximate topographic profile of the depression is shown in Figure 13.8. The southwestern side of the depression is prominently marked by a 10 m outcrop scarp in limestone identified as Lower Bobcaygeon by D.A. Williams. To the northeast, a second shallow scarp covered with overburden drops gradually another 4 m to a small creek running over exposed limestone identified as Upper Bobcaygeon by D.A. Williams. Northeast of the creek another 4 m outcrop scarp in the Upper Bobcaygeon rises to a meadow where the bedrock is covered with overburden.

An EM-31 survey line was established 30 m northwest of the property fence on the northwest side of Crookston road and approximately parallel to it. The line was 220 m long and extended from the flat-lying surface southwest of the depression to the high point of the meadow on the northeastern side. Hardly any variation in conductivity was noted over the entire line.

Due to the irregular topography, surface exposures of weathered bedrock, and dense cedar bush near the creek, seismic lines across the depression were impractical. Instead, three refraction lines were done in the direction of the strike of the depression (Figure 13.8). Only one line could be done in the fault zone depression itself. This was in a slight depression at the base of the 10 m scarp on the southwestern side. Another line was done in the meadow northeast of the depression, and a third line was done over the flat-lying limestone southwest of the depression.

Seismic depths and visual outcrops of limestone show a 2.5 m depression in the bedrock at the base of the 10 m scarp. In the meadow to the northeast, the bedrock more-or-less steps upward through one or two metres of overburden to the surface. Of significance also is the variation in velocity of the

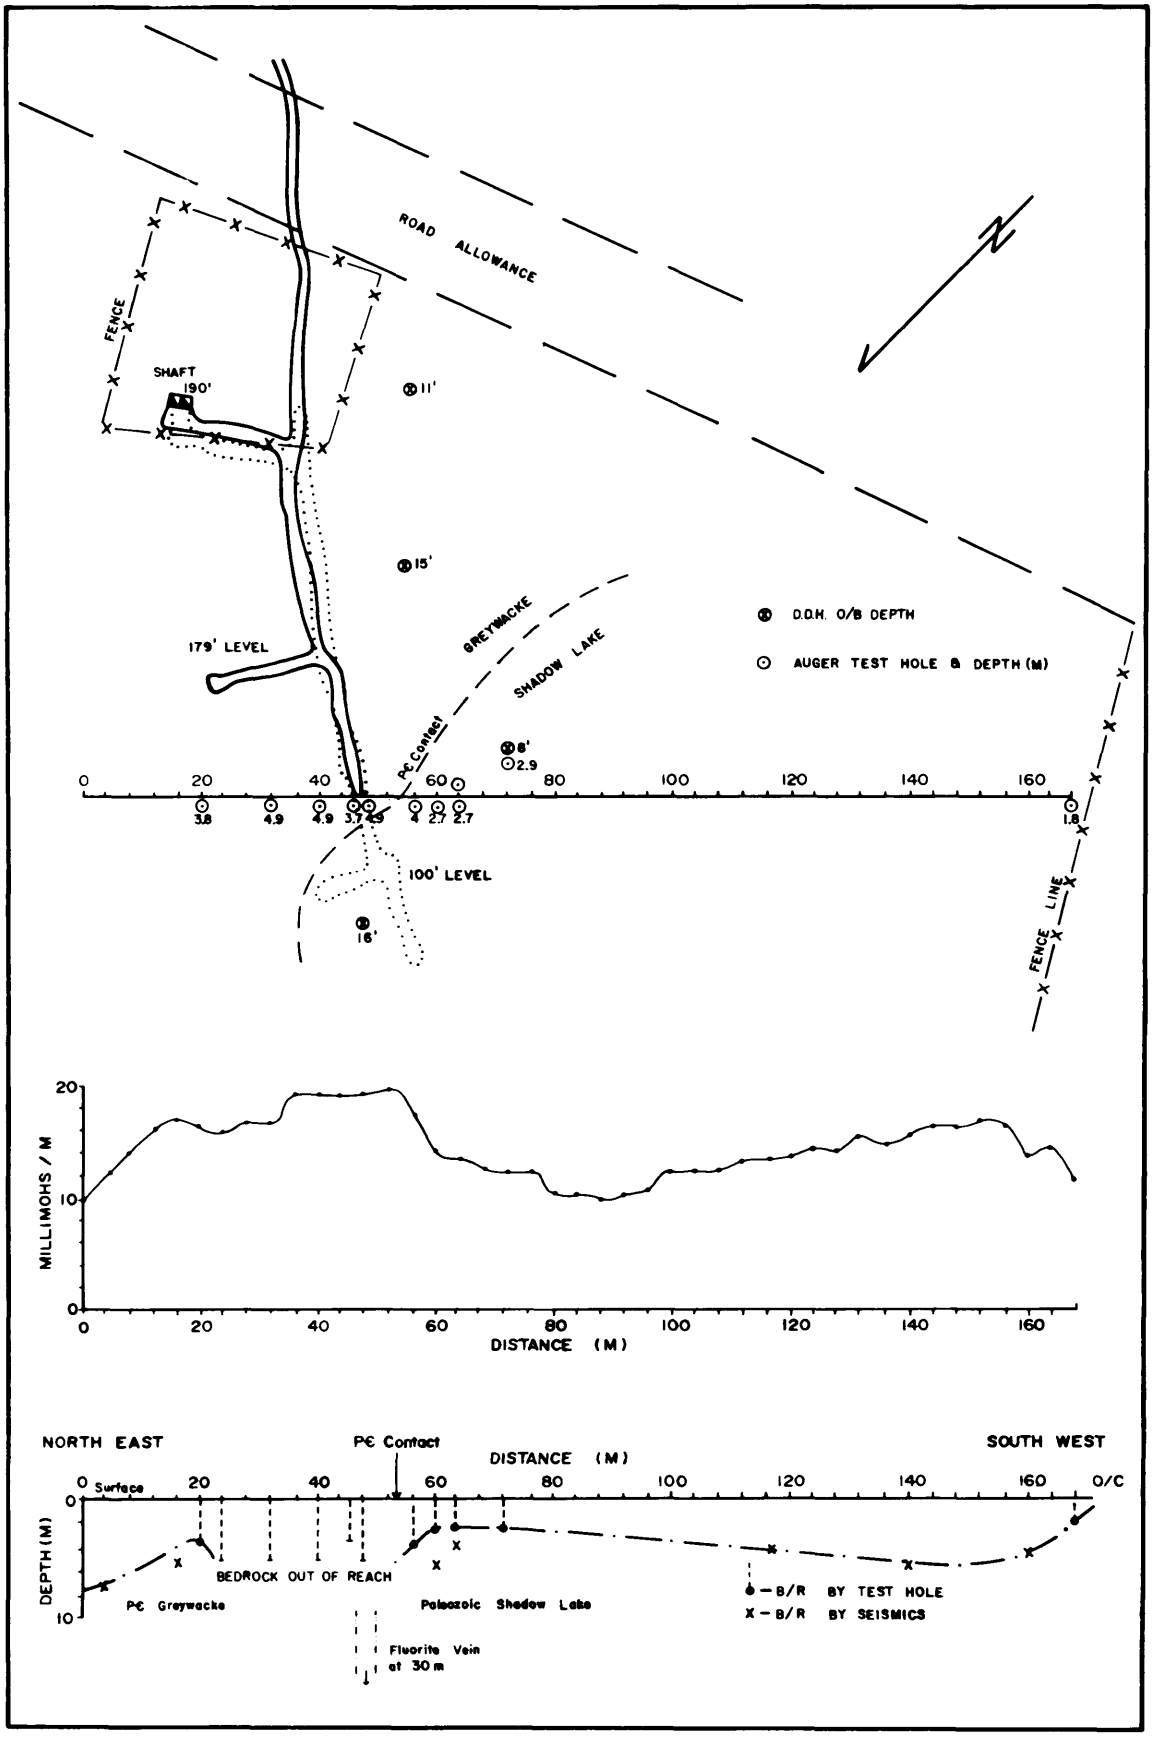

Figure 13.7 . Survey results for Bailey Mine Site

TABLE 13.3 SUMMARY OF SEISMIC REFRACTION RESULTS FOR BAILEY MINE SITE.

Line No. & Direction	Line Location	Topsoil Vel. (M/S)	Clay Vel. (M/S)	Bedrock Vel. (M/S)	O/B Depth (M)	B/R Depth (M)
Bailey-1 E-W	-4 m to 44 m	250	430	2670	1	7.0
Bailey-2 W-E	144 m to 48 m	350	880	3910	1	5.5
Bailey-3 F&R	12 m to 64 m	400	720	2200	1	5.5
Bailey-4 F&R	92 m to 140 m	340	no	data		
Bailey-5 F&R	60 m to 112 m	310	810	3090	1	4.0
Bailey-6 F&R	112 m to 164	375	750	4170	1	4.5

limestone. The velocity of 3030 m/s is typical for the weathered Lower Bobcaygeon southwest of the depression. At the seismic line at the base of the 10 m scarp, the velocity is only slightly higher (3470 m/s), indicating similar limestone. The velocity of the limestone northeast of the creek (4570 m/s) is significantly higher, consistent with the thick-bedded layers of Upper Bobcaygeon found here. This indicates that the main fault break must be southwest of the creek. According to D.A. Williams, the Upper Bobcaygeon exposed in the creek is down-faulted against the Lower Bobcaygeon at the southwestern side of the zone, and likely extends under the slope southwest of the creek. The main fault break, therefore, must be close to the base of the 10 m scarp. It seems most likely that the 2.5 m depression in the bedrock at the base of the 10 m scarp is the expression of the main fault break.

SURVEY RESULTS—BULLER SIDING SITE

Conductivity and seismic measurements were made and test holes were drilled along the northwestern side of concession 9 road, Hungerford Township, from the southwestern township line northeastward across lot 1. This site is just southeast of Buller Siding. A plan of the survey line along the road is shown in Figure 13.9. The bend in the road and survey line is not accounted for in plotting the EM and seismic results. The survey line and distances are taken to be in a straight line. At the township line, the limestone bedrock outcrops in a small scarp. To the northwest near Drag Lake, the bedrock outcrops in an abrupt high ridge. This has been identified by D.A. Williams as the lower section of the Bobcaygeon Formation. Just northeast of the end of the survey line, the bedrock outcrops again in a low ridge. The survey line was 495 m long between these two outcrops. Except for the till hill shown on Figure 13.9, the bedrock depression is covered by swamp and positive identification of the fault is not possible. However, the fault has to exist somewhere along the survey line.

Guillet (1964) has mapped the fault as crossing concession 9 road on the northeast side of a prominent till ridge, at the junction with the road leading northwesterly to Buller Siding. Closer examination of outcrops and topography indicates that the fault is probably on the southwest side of the till ridge in a swamp-filled depression.

The EM-31 measurements covered only the southwestern half of the survey line. The instrument was not available to complete the northeastern portion. The EM profile in Figure 13.9 shows a broad 15 mmho/m anomaly about midway between the township line and the till hill (160 m on the survey line). From previous experience with the EM-31, this would indicate a thickening of the overburden, but this does not seem to be the case here.

Ten seismic refraction lines were done at different overlapping sections of the survey line. Line BS-1 was shot in one direction only over a distance of 144 m. The remaining 9 lines were 52 m spreads shot in both forward and reverse directions. A summary of refraction results is given in Table 13.4. Profiles of seismic depths to the different subsurface layers are shown in Figure 13.9. The seismic results indicate three layers. It must be remembered that the seismic measurements are disturbed by road bed material and infilling of the swamp with large limestone blocks. It is not possible to distinguish between places where the swamp has been filled with large limestone blocks to make a base for the road, and *in situ* weathered limestone layers. The upper 1 to 2 m layer is overburden consisting of sand, silt, and gravel. The depths are a little uncertain, due to the effect of road bed material, in the horizontal direction. Below this is a variable depth layer up to 10 m thick, mostly consisting of what appears to be broken, and/or weathered limestone, according to seismic velocities. The lower layer is competent (not weathered) *in situ* limestone, distinctly identified by much higher seismic velocities. The profile of this layer shown in Figure 13.9 is *not* a profile of the bedrock surface exactly. It could well be that some of the depressions in the profile are actually filled in part with *in situ* weathered layers.

The profile of the competent layer is significant, because it should indicate any displacement of layers by faulting. The profile does show by its depressions and irregularities that the fault is southwest of the till ridge. The main break is most likely at about 240 m on the survey line, where the competent layer drops to a depth of 12 m. There is a possible second break at about 170 m where there is a distinct drop of almost 2 m. The fault location is also indicated by

*Only a portion of both Tweed and Napanee Districts are designated under the Pits and Quarries Control Act.

the seismic velocities of the competent layer. Southwest of the 12 m depression, the seismic velocity is about 5000 m/s, indicating solid thick-bedded layers. Northeast of the depression, the velocity decreases to about 4000 m/s or less, indicating a different sequence of limestone layers.

A test hole was drilled at 160 m on the survey line, where the competent layer was closest to the surface. Bedrock was encountered at a depth of 4.3 m, in agreement with the seismic depth. This confirms that the competent layer is actually the bedrock surface at this point. Test holes drilled at 272 m and 220 m on the survey line, encountered large rocks at depths of 0.3 to 0.5 m.

CONCLUSIONS

1. Phase 1 of this project (i.e. to detect the main fault break at sites where the Moira fault zone is known to exist) has been successful in that the main fault break has been located at three sites. At the Bailey Mine site, the location of the known fault was identified. At the Crookston road site and the Buller Siding site, the fault break was more precisely located within broad depressions.
2. The EM-31 primarily reflects overburden depth and is not useful for fault or fluorite vein detection. In future survey work, a deep penetrating EM system like the Geonics EM-34, or conventional resistivity equipment should be used.
3. The seismic method proved successful for locating and identifying the main fault break. Seismic depth profiling located the fault depression and seismic velocities identified different rock types on each side of the fault.
4. At the sites tested, the main fault break is close to, or at the base of, an abrupt scarp in limestone which marks the southwestern margin of the fault zone depression.
5. The results are encouraging and continuation of the project is warranted.

PITS AND QUARRIES OF NAPANEE, TWEED, AND BROCKVILLE DISTRICTS by Stuart M. Thatcher[1]

[1]Mineral Resources Supervisor, Napanee, Tweed, and Brockville Districts, Ontario Ministry of Natural Resources, Tweed

The Mineral Resources staff in Napanee commented on numerous severances, zoning by-laws, official plans, and amendments to the official plans and by-laws throughout the three districts. These dealt with the protection of viable aggregate reserves from incompatible land uses, and to ensure that proposed land use development would not preclude or hinder extraction. A total of 97 planning proposals were reviewed and received comment.

In 1985, 29 new applications were processed under the Pits and Quarries Control Act, bringing the three districts' total to 357 licenced pits and quarries. Table 13.5 shows the distribution of licenced pits and quarries and the licenced hectarage in those townships designated under the Pits and Quarries Control Act. The inspectors were heavily involved in processing 17 applications alone in Storrington Township, which was designated under the Act on July 1, 1984. However, the majority of the licences were issued in the fall of 1985.

A total of 73 townships are under the administrative responsibility of Napanee, with 42 townships being designated under the Act. Tables 13.6, 13.7, and 13.8 give the reported production figures for licenced operators in designated areas.

ABANDONED PITS AND QUARRIES STUDY

The abandoned pit and quarry study continued into 1985 with Prince Edward County being completed, along with Pittsburg Township. Table 15.9 shows the number of sites inventoried. These sites were then rated as (a) depleted, (b) moderate, or (c) substantial

INACTIVE HAZARDOUS MINE SITE INVENTORY

Over 100 sites in Frontenac and Hastings Counties were inventoried and evaluated as part of our ongoing program to determine if a site is hazardous, and to recommend remedial action when funds are available.

To date, 379 sites have been investigated since the inception of the program in 1983. In 1985, four sites in Frontenac Provincial Park were fenced to prevent inadvertent access by park users. These sites were old worked-out mica deposits. Table 13.10 summarizes the number of sites inspected and classified into three categories.

MINERAL RESOURCES—CARLETON PLACE AND CORNWALL DISTRICTS

The Pit and Quarry staff of Carleton Place District consists of M.A. MacDonald, Mineral Resources Supervisor, and A. Giles and T. McManus, inspectors.

Carleton Place District encompasses all of Lanark County and the Regional Municipality of Ottawa-Carleton, with a land base consisting of 563 521 hectares and 22 geographical townships.

The Mineral Resources staff are employed on many projects improving and speeding up rehabilitation on all pits and quarries. Annual reviews of all licenced properties are a high priority. Staff comment on all aspects of plan review and ensure that townships are updated on mineral resources potential within their respective boundaries.

There are many abandoned pits and quarries in the district, and no remedial action has been taken to date on inactive hazardous mines and shafts, due to financial constraints.

Table 13.11 lists the total number of licenced quarries, pits, and pits and quarries, in Carleton Place District, and Table 13.12 lists the reported production of aggregate by Township for 1981, 1982, and 1983.

The pit and quarry staff of Cornwall District consists of B.W. McCue, District Lands and Mineral Resources Supervisor, and D. Willis, Inspector.

Cornwall District works closely with municipalities and the Ministry of Municipal Affairs and Housing at both the plan input and review stages to ensure that mineral resource activities are considered in the planning process (severences, subdivisions, official plans, zoning by-laws, etc.)

Table 13.13 lists the number of licenced pits, quarries, and pits and quarries by county and township for 1985.

Table 13.14 lists the aggregate production from licenced pits and quarries for 1984 from Cornwall District.

14. Central Regional Geologist Area, Central Region

Mahendra Narain[1] and Jackie Burkart[2]

[1]Regional Geologist, Ontario Ministry of Natural Resources, Richmond Hill

[2]Resource Geologist, Ontario Ministry of Natural Resources, Richmond Hill

INTRODUCTION

During 1985, the Central Regional Geologist placed greater emphasis on further assessment and development of the Region's aggregate, building stone, clay, and shale resources. This was as a result of a growing interest in building stone products, quality aggregates, ceramic wall and floor tiles, and roofing tiles. Several new projects have been initiated to improve data on the resources to better serve potential investors.

Geoscience information and consultative services were provided by the Regional Geologist's office at Richmond Hill, and by the five district offices at Fonthill, Maple, Lindsay, Cambridge, and Midhurst. Various provincial government agencies, the aggregate industry, private consulting firms, mining companies, and the general public were some of the typical user groups. Requests for these services related to mining and petroleum resources, alloy materials, specialty aggregates, etc. More interest was indicated in mining-related investment opportunities in the Central or neighbouring regions.

The mineral resources outlook remains optimistic in Central Region, with an increase reported in both aggregate and gypsum production in 1985. The Region has 867 licenced pits and quarries and 3 gypsum mines.

Inter-program and inter-ministry consultations have been increasing at both the regional and district levels. The Regional Geologist continued to administer geological programs related to geoscience information, data collection, and mineral resource management. Technical direction and support was provided for District Mineral Resource Programs.

Current staff at the Regional office includes: Martin Groneng, Regional Lands and Mineral Resources Coordinator; Jackie Burkart, Resource Geologist; and June Feeney and Barbara Crowe, Secretaries.

Geological staff at the district offices include: John Frazer, Niagara; Amar Mukherjee, Maple; Tom Cumby, Lindsay; Bill Fitzgerald, Huronia; and Don Routly, Cambridge.

REGIONAL GEOLOGIST'S ACTIVITIES

RESOURCES AND LAND USE PLANNING

A large part of the Regional Geologist's time was spent coordinating several mineral resources projects in the Region. A study to assess the suitability of clay and shale resources of the Central Region for brick and tile manufacture was initiated in 1984. This was done in response to several inquiries from potential investors looking for suitable resources. In 1985, the study was expanded to include the suitability of selected clays and shales of Central and Southwestern Regions of the Ministry of Natural Resources. Samples representing shales of the Blue Mountain, Georgian Bay, Queenston, Cabot Head, and Arkona units, two Pleistocene glaciolacustrine clays, and one recent alluvial clay were collected and tested. Laboratory testing was carried out by a private consulting firm at the CANMET Lab in Ottawa and in the Land Resource Science Labs at the University of Guelph. All sampling and testing has been completed and the first draft of the report is under review. Study results have been very encouraging, and several sites were found to have suitable resources. The 1984 study is now available as Open File Report 5571 (Kwong *et al.* 1985). The 1985 study will be available as an Open File Report in early 1986.

The Regional Geologist assisted the district offices in the planning and implementation of aggregate resources evaluation projects. These projects were designed to collect data to promote conservation and proper utilization of the Region's mineral resources, and to assist both levels of municipal governments in their planning processes.

The Regional Geologist conducted a preliminary examination of licenced quarries and unlicenced sites for potential building stone resources. Some samples from sites in Lindsay, Cambridge, and Maple Districts were collected, cut, and polished, to determine the quality of the rock as a building stone. The results of this survey have been encouraging and more extensive examination and testing of these resources is planned for 1986.

Another project has been initiated to reassess the Region's potentially available aggregate resources. All of the mineral aggregate areas identified in the district guidelines are being re-evaluated with the intention of creating a more accurate inventory of our Region's potentially available aggregate resources. This assessment involves researching Ministry of the Environment water well records, Ministry of Transportation and Communications data on tested properties, data collected by the Aggregate Assessment Office, and hopefully some field testing of selected aggregate areas in 1986. The new data would aid ministry staff in plan input and review functions, as well as help regional municipalities update mineral aggregate information in their official plans.

An inventory of all past and present mineral commodities in Central Region was undertaken in 1984 and 1985. The inventory is in the form of a map, locating all of the past and present oil and gas and mineral related activities. The map, with notes, is expected to be available in Summer, 1986.

CONSULTATION AND EDUCATIONAL SERVICES

The Central Region office and its five district offices continued to provide consultation services related to geology, mineral resources, and legislation. Some of the various inquiries were related to mineral rights, claim staking, and mining and minerals in general. Following are some of the beneficiaries of geological and mineral resource inputs made by Regional and District staff: local and regional municipalities, Ministry of Transportation and Communications for their

aggregate sources lists, township aggregate inventories of the Ontario Geological Survey, Ministries of Labour, Environment, Agriculture, Housing, the Conservation Authorities, Ontario Hydro, and the Niagara Escarpment Commission.

Central Region, in conjunction with the Ontario Geological Survey, organized and erected a natural building stone display at the Woodfire '85 Exhibition at Malton in May, and at the Toronto Home and Do-It-Yourself Show in October. The display, which included many of the natural stones of Ontario, as well as ceramic tiles, was set up in response to a renewed interest and increasing demand for natural building stone products. Public interest in building stone, and response to the exhibit, were immensely encouraging.

District staff arranged various geological and mineral resource related displays, tours, and seminars for numerous groups such as geological and mineral clubs, junior rangers, high school and post-secondary students, ministry personnel, pit and quarry operators, and other interest groups.

PROPERTY EXAMINATIONS

The Regional Geologist along with district, main office, and Southwestern Region staff, and consultants, examined and sampled several clay and shale deposits in Central and Southwestern Regions.

The Regional Geologist accompanied Lindsay District staff on a field trip to identify potential hazards in areas of past mining and exploration activity in Belmont and Harvey Townships.

District staff have conducted extensive field evaluations of both licenced and other resource areas, and this work will continue for several years to ensure availability of resources, and to determine their quality and quantity for possible extraction.

GEOLOGY AND MINING–RELATED ACTIVITIES

Central Region boasts a wealth of mineral resources which includes sand and gravel, limestone, dolostone, sandstone, shale, clay, gypsum, traprock, peat, and even some gold and oil and gas. A small amount of sulphur is produced in Cambridge and Maple Districts as a by-product of oil and gas refineries. The majority of minerals produced in Central Region are used in the manufacturing and construction industry, and the Region maintains its status of being the largest producer of structural materials in the Province.

Approximately 56.2 million tonnes of aggregate materials were produced in the Region in 1984, a 17.5% increase over 1983 production. The consistent improvement in production is due to improved economic conditions in the construction industry. The aggregate industry is even more optimistic about their outlook for 1986.

The Fairmont Granite Quarry in Belmont Township reports a nil production for 1985. Operation of the quarry was suspended in 1984 due to excessive fracturing of the stone with increasing depth. No gold production was reported for 1985 by Lasir Gold Incorporated at the Cordova Mines in Belmont Township.

Gypsum is produced at three locations within the Region: Drumbo, Hagersville, and Caledonia. Production at these gypsum mines has been improving considerably over the past years; one company has expansion plans well under way, and a new shaft is expected to open in 1986.

Following are highlights of some of the mineral producers and consulting firms within Central Region, as reported by the respective companies.

LASIR GOLD INCORPORATED, TORONTO

Lasir Gold Incorporated has entered into a joint venture syndicate agreement with an Ontario private company, 589026 Ontario Incorporated (CWT Division). CWT Division has a long term renewable contract with the City of Toronto to remove the Sewage Sludge Incinerator Ash (SSIA) from the storage lagoons at Ashbridges Bay on the Toronto harbour front. Ministry of the Environment (MOE) approvals to remove the SSIA from Ashbridges Bay, process it, and dispose of the residue, are being negotiated. Early approvals are anticipated.

A processing plant site on the harbour front, on property owned by the Harbour Commission and subleased from Esso Canada Limited is being readied for the installation of the processing facilities to treat the SSIA for the recovery of the contained precious metals. Gold and silver will be recovered by conventional leaching methods. Average values from sampling done by Noranda Incorporated of the SSIA in the lagoons are reported as 0.15 ounce gold per ton and 7.89 ounces silver per ton. Between 80 and 100 tons of SSIA are produced on a daily basis at Ashbridges Bay. Additionally, there are some 100 000 tons on hand which must be treated and disposed of to enable the continued storage of SSIA being produced. Accordingly Lasir Gold, as the operator, proposes to treat SSIA on the premises subleased from Esso Canada at the rate equivalent of 300 tons per day.

Plans to complete the plant at the company's Cordova Mines location to enable the treatment of some 70 000 tons of old stamp mill tailings grading 0.04 ounce gold per ton are underway so that a start-up can be made early in 1986. Plant completion costs are estimated to be in the order of $180 000, with operating costs estimated at $6 per ton. Income generated from the Cordova Mines plant will be 100% for Lasir Gold's account. There are under-

ground reserves on the order of 150 000 tons grading 0.16 ounce gold per ton at the Cordova Mines Property. An exploration agreement is presently under negotiation to develop additional reserves that may exist underground and from other locations in the adjoining areas.

RICE & McHARG QUARRIES LIMITED, GEORGETOWN

It has been a relatively good year with increased demand for natural Credit Valley building stone. While we have sold more material, we are in the process of licencing additional property for extraction and have run into quite a significant amount of red tape and had to limit our extraction. We hope to have an additional 10 acres licenced by 1986 and will hope to be able to provide our steady customers with their usual requirements for stone.

Our operation is mostly manual extraction, and modernization changes are very minimal at this point in time. We are, however, intending to start some rehabilitation procedures to improve the land value and quarry operations.

Overall, there are no significant changes, but demand for stone seems to have resurged and we hope to continue to provide this rather limited material to those interested.

GORMLEY SAND & GRAVEL LIMITED, GORMLEY

Our tonnage shipped during 1985 will be approximately the same as 1984. Our deposits in the Uxbridge area are generally going sandy, as are most of the other operators'.

We have recently purchased an underwater drag scraper to enable us to mine reserves that are currently below the water table, starting with our Tottenham pit located on the south side of Highway 9. After approximately four years, this equipment will be then moved to our pit located on the 7th concession of Whitchurch-Stouffville, to remove the underwater reserves at this location.

The quarry located in Carden Township continues to supply material for industrial and commercial growth in the northeast of Metro.

WALKER BROTHERS QUARRIES LIMITED, NIAGARA FALLS

Walker Brothers Quarries is a limestone surface mine located on the corner of Mountain Road and Thorold Townline Road in Niagara Falls.

We presently employ 18 personnel which are directly related to the production of crushed stone. As of the end of October, we have produced 460 000 tonnes. We plan to produce until December, which will give us a yearly production of approximately 540 000 tonnes. We operate three extraction faces ranging from 20 feet to 40 feet. We have made no major changes in our production system.

In 1986, we will probably experience identical market conditions in our area.

VINELAND QUARRIES & CRUSHED STONE LIMITED, VINELAND

Vineland Quarries is a limestone surface mine located on the corner of Fly Road and Regional Road 24 in Vineland.

We presently employ 11 personnel which are directly related to the production of crushed stone. As of the end of October, we have produced 440 000 tonnes. We plan to produce until December which will give us a yearly production of approximately 540 000 tonnes. We operate one extraction face ranging from 15 feet to 25 feet. We have made no major changes in our production system.

In 1986, we will probably experience identical market conditions in our area.

ARRISCRAFT CORPORATION, CAMBRIDGE

Under the name of Adair Marble Quarries, Arriscraft Corporation quarries a dolomitic limestone from the Amabel Formation for use as dimensional building stone.

Over the last few years there has been a very significant revival in the interest in dimension stone for major commercial buildings. We have supplied a number of major projects in the last year to a year and a half. These include:

1. The Ontario Courthouse. 70 000 square feet.
2. Numerous smaller commercial projects of approximately 20 000 square feet.
3. Currently specified for the supply of Adair stone on the new Canadian Chancery to be built in Washington, D.C. (180 000 square feet).

Actual production at the quarry in 1985 will exceed 20 000 metric tonnes. This is well in excess of any past year. We foresee this continuing indefinitely in the future.

In conjunction with the supply of marble for the Canadian Chancery in Washington, we anticipate building a major marble fabrication plant in Cambridge. This should proceed in early 1986. We believe that with these facilities in place we will be in a position to become one of the dominant natural stone suppliers on the continent.

FRANCESCHINI BROTHERS AGGREGATES LIMITED, MISSISSAUGA

We are pleased to report that 1985 sales will exceed our estimated forecasts by more than 20%, as recoveries in most sectors of the construction industry were prevalent.

Operations varied little from the past two years, other than the volume of shipments and capital expenditures were again restrained, other than the purchase of a new seven cubic yard loader for our Caledon operation.

It appears consumptions of aggregate within our shipping area will remain in line with 1985 levels.

UNITED AGGREGATES LIMITED, BRAMPTON

Armbro Aggregates has changed ownership and is now a Division of United Aggregates Limited. This took place September 1st, 1984, and includes the sand and gravel operations at Caledon and Brampton, Ontario; the limestone quarry operation at Ottawa, Ontario; and the Armbro Ready Mix operation in Mississauga, Ontario.

On June 15th, 1985 United Aggregates Limited purchased the Indusmin Quarry operation at Acton, Ontario, from Falconbridge Limited.

The Acton quarry had an extensive overhaul of plant and equipment and was re-opened September 1st. We are anticipating 2 million tons of production next year.

At Caledon our production should remain at about 2.5 million tons.

Our Ottawa quarry production should drop from 1.2 million tons in 1985 to about 800 000 tons in 1986.

ACRES INTERNATIONAL LIMITED, NIAGARA FALLS

Acres is a major international consulting engineering company that has provided quality engineering to its clients for over 60 years. Operations have spread throughout Canada and the United States, and to 60 countries in Central and South America, Africa, and Asia. Clients include major public utilities, large and small industrial concerns, all levels of government, and major foreign aid financial institutions such as the World Bank, the Asian Development Bank, the Canadian International Development Agency, and the United Nations Development Program.

Acres has been a leader in the unique development of Canada's vast resources and infrastructure which has employed capital, technology, and engineering skills from throughout the world. Acres' highly qualified staff employs worldwide state-of-the-art engineering technology. Its over 900 engineers, scientists, economists, technical specialists, and administrative staff are drawn from many countries and engineering traditions, and provide a synthesis of international major projects and industrial development experience.

Acres was contacted by the Ministry of Natural Resources to carry out a water resources inventory of Ontario. Extensive data was available on both the available water supplies of Ontario, as well as the uses of that water. This information was scattered in both public and internal government reports in different government departments and with various levels of accessibility.

Acres was commissioned to synthesize the available information into one document, utilizing map and graphical presentations as appropriate, so that the overall water quantity situation of the Province would be available to those with limited time.

The final document included 71 pages of text, graphs, and maps describing surface water resources, groundwater resources, and water uses in Ontario. Colour was used throughout to permit, through the use of colour changes and shading, complex data and interrelationships to be presented in a comprehensive and aesthetically pleasing map.

Information presented is based on data directly available, such as river flows and precipitation, as well as calculated information such as evapotranspiration. Water use information covers both consumptive and non-consumptive uses. The latter includes navigation and recreation.

The complete project including design, concept development, data collection and analyses, art work, and printing of 5000 copies was completed in 28 weeks.

DOMINION SOIL INVESTIGATION INCORPORATED, SCARBOROUGH

In the field of *geotechnical engineering* we have successfully undertaken subsurface explorations for a variety of residential and industrial buildings, ranging from investigations for individual houses to high rise buildings which are underlain by several basement levels. The variety of projects range from residential subdivisions to the proposed new Justice Centre in downtown Toronto, and industrial facilities such as the Chrysler Canada plant expansions in Windsor. This Company has undertaken investigations for sewer and watermain installation; for evaluation of the stability of both cut and natural slopes, and design of remedial measures for landslides; for design of highway and airport paving structures; for evaluation of granular reserves; terrain evaluations; and investigations for projects in permafrost areas. In undertaking the field explorations for this work, we have used *in situ* testing equipment, such as the static cone and flat dilatometer, to complement the conventional exploratory techniques.

This Company also undertakes *control testing* and approval of *construction materials and inspections*. We are approved by the Canada Standards Association (CSA) for concrete testing, and partake in the Ministry of Transportation and Communications' schemes for asphalt mix design and control, and chloride level in concrete. We undertake the supervision and control of placement of engineering fills, and site preparation. This Company also has on staff personnel who are qualified to carry out inspections of structural steel, built-up roofing, evaluations of the condition of concrete structures, and existing roof applications.

MacLAREN PLANSEARCH, TORONTO

The company provides services in Field Testing for hydrogeological and geological evaluations:

a) Drilling and sampling, installation of piezometers and other subsurface monitors in surficial sediments.

b) Drilling and drill stem tests to assess fracture flow hydrology in rock. Includes packer tests (falling head constant, head and pulse testing using electronic equipment), installation of deep piezometers, fracture logging for overall fracture patterns to assess flow directions.

c) Permeability testing, including pump testing, variations on slug tests.

d) Chemical sampling for standard parameters and trace organics.

e) Sampling for terrain analysis, aggregate inventories.

f) Geophysics: downhole and surface electromagnetic methods, downhole gamma, seismic, etc., for water supply studies and depth to bedrock location of contaminants plumes.

g) Geological mapping of surficial deposits and bedrock.

Field data are compiled and analyzed and comprehensive reports are written, often in conjunction with other disciplines. Data analysis is supported by computer modelling. These vary from use of large computer models on our mainframe to small models run on the microcomputers. Extensive data analysis is required for pump test and slug test results. Often analytical solutions are employed as a predictive device. Remote sensing techniques are used as support for the field work.

In addition, MacLaren has a fully equipped laboratory which has the capacity for soils analysis and a full range of chemical analysis, including trace organics.

In-house expertise includes biology, air environment, nuclear studies, waste treatment, process design, systems division, and waste management.

As part of Lavalin, we have immediate access to geotechnical expertise.

Major projects with earth science involvement in 1985 include:

a) The Region of Peel Solid Water Management Study is concerned with finding a new sanitary landfill site in northwest Brampton. The earth science involvement included extensive drilling to confirm bedrock and install piezometers in seven areas across the Region; terrain analysis for sediment types; permeability testing and water level monitoring for an assessment of groundwater flow conditions; and assessment of the optimum site based on geological parameters.

b) Tanenbaum Brothers Investments Limited The 801 Lakeshore Boulevard site was once a Domtar coal tar plant and over the years extensive coal-tar-related substances such as polynuclear aromatic hydrocarbons, anthraquinone, and phthalic anhydride had been disposed of on the site. The hydrogeological aspects of the study carried out by MacLaren involved characterizing the site hydrogeology and patterns of contamination. The proposed remedial works were designed by Cutforth White & Associates in conjunction with MacLaren, and involved the capture of groundwater flowing off the site using the proposed new building's tile drain system. This unique solution necessitated obtaining the Minister of the Environment's approval under Section 45 of the Environmental Assessment Act.

c) Canadian General Electric—Davenport Site Remedial works to contain and recover PCB-contaminated oils and other organic chemicals floating on groundwater were designed and constructed. The contaminated oils were recovered using large diameter wells with two pump systems, one for lowering the water table and the other for collecting oil. The wells were pump tested and the data used as input to a simple computer model for the prediction of further well spacings.

C. MIRZA ENGINEERING INCORPORATED AND STRATA ENGINEERING CORPORATION, DON MILLS

Two important projects were completed during 1985.

The first was a study of the geological "Type" exposure on the north slope of the Don Valley Brickyards. This study was commissioned by the Ontario Heritage League under the auspices of the Ministry of Citizenship and Culture. It involved mapping of the exposed face, sampling the various exposed strata (often precariously for our geologists), and limited testing. The purpose of the project was to identify the minimum slope requirements for stability and erosion control, as well as to provide a conceptual plan for the preservation of the exposure for future geological and educational purposes.

The report addresses the geological features of particular interest to the scientific community. It includes an analysis of slopes cut back to various angles, and includes a summary of the history of slope failures along the Don Valley.

The second project was a study of alternate sources for sand and gravel to meet the demands for these materials in the Regional Municipality of Niagara to the Year 2010 and beyond. Partners in this study were Martini and Associates of Guelph and Peat Marwick of Toronto. The Planning Department of Niagara Region carried out a review of land based resources, while Martini and Associates examined the potential for dredged sand from the Niagara Bar. Peat Marwick and Partners carried out economic analyses of transportation modes for trucking or shipping imported materials into the Region.

The fundamental basis of the study, as given by the Region, was to assume that the Fonthill Kame, which now supplies a major portion of the aggregates for concrete, roads, winter sanding, and other uses, would no longer be available. Demand forecasting involved examination of statistics for population growth, propensity to form households, construction activity levels, and other vital data. Emerging conservation technologies were also examined for their impact on aggregate consumption; technologies such as recycling, materials modification, and the use of other materials such as slag, foundry sand, etc.

The study concluded that there would be a concrete sand deficiency, which could be made up if the technology relevant to manufactured sand could be developed to a reliable state. The study also recommends further areas for research before any irrevocable decisions are made with respect to the future disposition of the Fonthill Kame.

Ongoing work during 1985 included continued research on Aquifer Thermal Energy Storage at the Scarborough "Canada Centre" site, where instrumentation is now complete and commissioning is well underway. The firm also investigated the potential for Micro-Hydro electric power applications at sites in Orangeville. Research is also underway on coupled heat-moisture flow, modelling of mine crown pillars, and landslide stabilization.

We wish to acknowledge the support and encouragement of many individuals in government and the private sector who were instrumental in helping us undertake these studies and bring them to fruition.

STAKING AND EXPLORATION

Exploration and development activities in the Central Region increased in 1984. Most of these activities included diamond drilling, airborne geophysics, development drifts, and miscellaneous. Total exploration and development expenditure for 1984 was $339 804, up 14% from 1983.

In 1985, eleven new mining claims were recorded and eighteen claims cancelled, bringing the current total to fourteen mining claims. All of these claims are in Belmont Township, Peterborough County. There are also twelve mining leases in Belmont Township. Over 200 man-days of assessment work has been filed on the unpatented mining claims in 1985.

REGIONAL GEOLOGICAL EVALUATION PROJECTS

SANDSTONE RESOURCES STUDY

Both stages of this study have now been completed and the final publication for Stages I and II were released as Open File Reports 5363 and 5549 respectively.

SHALE AND CLAY RESOURCES STUDY

This study was initiated in late 1984 to assess the suitability of this Region's selected clay and shale resources for their ceramic properties for wall, floor, and roofing tile manufacture. This year the study area was expanded to include the clays and shales of Southwestern Region as well. All tests have now been completed for this second stage, and the first draft of the report is under review. The final report for the second stage should be available in 1986 as an Open File Report. Open File Report 5571 on the 1984 study has now been released.

TOWNSHIP AGGREGATE INVENTORIES

To date, a total of 65 aggregate inventories have been completed and published for this Region. Publications for the towns of Lincoln, West Lincoln, Grimsby, and Haldimand; townships of Wainfleet, Woolwich, Cavan, North Monaghan, and South Monaghan; and the cities of Guelph, Kitchener, Waterloo, and Cambridge were released in 1985.

PROJECTS UNDER THE MINING SECTOR WORK PROGRAM AND ONTARIO YOUTH OPPORTUNITY PROGRAM

Lindsay, Niagara, Maple, and Cambridge Districts have completed a number of projects under this program. These projects were designed to collect additional mineral resource and statistical data for planning and resource management.

Maple and Lindsay Districts are examining planning constraints to determine their impact on mineral aggregate resources in the Durham Region. Maple is conducting a similar project for the Region of York.

Cambridge District has completed a Floodplain Aggregate Study, carried out by Planning Initiatives and Frances Nicholas Limited of Kitchener, Ontario.

Maple, Lindsay, and Niagara Districts have completed a commodities survey of their areas.

Niagara District has completed studies on land use trends over the past thirty years on the Fonthill Kame area; Paleozoic and Quaternary geology of Shorthills Provincial Park; and detailed drift thickness maps of the entire District at 1:10 000.

RE–EVALUATION OF POTENTIALLY AVAILABLE AGGREGATE RESOURCES IN THE REGION

A cooperative effort between Region and Districts on this project has been started in 1985. Due to lack of funding, this project will be spread over several years and will be completed in-house.

PUBLIC AWARENESS PROGRAMS

Regional office staff, along with Ontario Geological Survey, presented an exhibit on natural building stone at the Woodfire '85 Show in Malton in May, and again at the Toronto Home and Do-It-Yourself Show in October.

Niagara District staff led several tours of the Queenston Quarry Property of Steetley Industries to provide assistance to the operators in the development of a new comprehensive rehabilitation plan for the property. Tours were given for Ministry staff, the Ontario Heritage Foundation, and a Canadian Broadcasting Corporation (CBC) film crew for the program "The Nature of Things". Lindsay District staff gave a presentation on the District's Mineral Resources program to the Junior Rangers at Coldsprings Camp, followed by a field trip to TRT Industries Limited in Manvers Township. Maple District staff conducted geological tours for Junior Forest Rangers and the Township of Uxbridge municipal staff.

Regional and Maple District staff conducted a tour for visitors from Malayasia who were in Canada to study modern quarrying techniques and building stone products.

SUMMARY OF FIELD WORK BY THE ONTARIO GEOLOGICAL SURVEY

I. Peter Martini and James P. Kwong of Martini and Associates of Guelph, Ontario. conducted a sedimentological examination and geological mapping to identify depositional environments of selected clay and shale resources. Samples of these resources were subjected to ceramic testing at CANMET Labs at Ottawa for their suitability for manufacture of ceramic products.

P.F. Karrow of the University of Waterloo continued mapping of Quarternary geology of the Brampton Sheet.

GEOSCIENCE RESEARCH GRANT PROGRAM

R.N. Farvolden, J.P. Greenhouse, and P.F. Karrow of the University of Waterloo continued their work under Grant 128 on Subsurface Quarternary Stratigraphy Using Borehole Geophysics. The project began in 1982. The study has as its dual objectives obtaining information on the Quarternary stratigraphy of the Kitchener-Waterloo region, and improving techniques of recording and interpreting geophysical logs for this purpose.

M.C. Miles, E.C. Appleyard, K. O'Shea, P. Lapcevic, S.K. Frape, and P. Fritz of the University of Waterloo continued their work under Grant 148 on Geochemical Study of the Salina Group of Southern Ontario—Isotopes, and Major and Minor Elements.

INTRODUCTION

Southwestern Region is unique in the Province as the conventional mineral resources program is combined with the petroleum resources program to provide a multi-faceted approach to encouraging exploration for and development of mineral resources within the Region and hydrocarbons within the Province. The three main aspects of the program include geological, engineering, and enforcement functions. All geological aspects of the program are carried out from the Petroleum Resources Laboratory while the engineering and enforcement functions and program administration originate from the Regional office.

The Petroleum Resources Laboratory, located at 458 Central Avenue, London, doubles as the Regional Geologist's office. Staff include R.A. Trevail, fulfilling the dual role of Chief Geologist of the Lab and Regional Geologist; B.H. Feenstra, Mineral Resources Geologist, and M. Campbell, Petroleum Resources Lab Technician. Contract staff employed at year end were: C. Palmer, M. Bernardo, D. Perkin, P. Pakvis, and J. Sando. Other contract staff employed during the year included C.L. Trussler, J.A. Barnicke, M.T. vanDeursen, D.K. Parker, and L. Walkom.

The Regional office, located at 659 Exeter Road, London, is staffed by P.A. Palonen, Provincial Petroleum Supervisor-Regional Mineral Resources Coordinator; R. Rybansky, Reservoir Engineer; H.E. Habib, Reservoir Engineer; K. Kinnear, Geotechnical Engineering Assistant; P.A. Wright, Administrative Assistant, Petroleum Resources; I. Cameron, Drafter, C. Hesselmans, Acting Systems Analyst; F.E. Kamps, Acting Data Processing Technician; and M.T. vanDeursen, Program Secretary. Contract staff include C.M. Rose and B. Davidson.

Mineral Resources Supervisors, T.R. Carter in Wingham and J.W.E. Lau in Aylmer, provide geological expertise to the districts. Petroleum Resources Inspectors, responsible for enforcement of the Petroleum Resources Act, are located at the District Offices in Aylmer, Chatham, and Simcoe. Pits and Quarries Inspectors, responsible for enforcement of the Pits and Quarries Control Act, are located at the District Offices in Aylmer, Chatham, Owen Sound, Simcoe, and Wingham.

REGIONAL GEOLOGIST OFFICE ACTIVITIES

On an average, 600 to 700 people per year utilize the Petroleum Resources Laboratory facilities personally to gather information, both geological and regulatory, examine drill cuttings and core, and discuss ongoing or potential exploration and development programs (both mineral and hydrocarbon) with professional staff. To meet the continually growing demand for information and technical expertise, staff have initiated a number of programs designed to increase base knowledge of specific mineral deposits occurring within the Region and the potential markets for those deposits.

The first part of this report summarizes Petroleum Resources activities and the second part summarizes Industrial Mineral Resources activities in the Region.

PETROLEUM RESOURCES ACTIVITIES

The Petroleum Resources Laboratory is a repository for all subsurface geological samples consisting of drill cuttings and cores obtained from the drilling of wells penetrating geological formations of Cambrian or more recent age, and, more generally, those drilled as part of petroleum exploration and development programs. Following expiry of the confidentiality period as provided for by regulation under the Petroleum Resources Act, all samples, cores, geophysical well logs, and related information submitted to the Section are placed in the public domain.

Hydrocarbon Energy Resources Program

Work continued in 1985 on the 40-month long study of Ontario's conventional oil and gas reserves and potential, an integral part of the Hydrocarbon Energy Resources Program (HERP) funded by the Ontario Ministry of Treasury and Economics under the Board of Industrial Leadership and Development (BILD). A report titled "Evaluation of the Conventional and Potential Oil and Gas Reserves of the Devonian of Ontario" (Bailey and Cochrane 1985) was released in September by the Ontario Geological Survey as Open File Report 5555, along with 86 Preliminary Maps at a scale of 1:100 000 showing the regional structure and/or isopach contours of the following horizons:

1. Structure Top of Pre-Hamilton Devonian Carbonates
2. Isopach Gross Columbus Sandstone Section
3. Structure Base Columbus Sandstone
4. Isopach Oriskany-Springvale Sandstone
5. Isopach Sylvania Sandstone
6. Structure Top Devonian Sulphur Water-Porosity
7. Isopach Top Devonian Carbonate to Top Sulphur Water-Porosity

In addition to these, detailed oil and gas pool maps at a scale of 1:20 000 were prepared for the following pools:

1. Bothwell-Thamesville
2. Florence-Oakdale

3. Glencoe
4. Oil Springs
5. Petrolia
6. Plympton-Sarnia
7. Rodney
8. Romney
9. Wallacetown
10. Watford-Kerwood
11. Wilsoncroft

Both the Silurian Sandstone and Silurian Reef Complex reports are in the final stages of preparation for publication and should be ready for release in the first half of 1986. Work continued on the final report, a summary of the findings of the project including a calculation of the current known reserves and a projection of the potential resources.

Computer Innovations

Computerization within the Petroleum Resources Section moved ahead dramatically with completion and installation of the Ontario Petroleum Data System (OPDS). Developed by DataPlotting Services Incorporated (DSI) of Toronto, OPDS consists of a powerful suite of applications programs integrated with a database management system on a DEC VAX computer located at DSI's office in Toronto. The System can be accessed directly at this central site or from IBM PC's at local sites. The IBM PC's are also used for local data entry and verification and other local applications.

OPDS is capable of producing reports, statistics, graphs and charts, well location maps, contour maps, and perspective views of geological structures utilizing information stored in the system for approximately 13 000 wells.

In June of 1985, approval was granted by Management Board of Cabinet for Southwestern Region to acquire a DEC VAX 11/750 computer and associated hardware and software. The Petroleum Resources Section is the current primary user and is in the process of enhancing the OPDS to meet the requirements of the Section as a whole. The updated system, to be known as the Petroleum Resources Data System (PRDS), will incorporate programs to facilitate the regulatory processes of well permitting, bonding, licencing, and Lake Erie expenditures and credits as well as a petroleum engineering software package to allow a rapid yet sophisticated method of hydrocarbon reservoir analysis. The Section will use the system to design programs which both promote the search for, and regulate the production of, hydrocarbons in Ontario.

Ontario Energy Board

One important aspect of the Petroleum Resources program is to provide technical assistance to the Ministry of Energy and the Ontario Energy Board (hereafter referred to as "the Board") on specific energy-related matters, particularly those dealing with exploration, development, and production of oil and gas pools. Such technical assistance ranges from verbal consultation on matters of procedure through to preparation of technical reports and presentation of findings contained therein at formal Board hearings.

During 1985, Petroleum Resources personnel participated in one formal hearing (E.B.O. 111), provided technical advice to the Board counsel at a second formal hearing (E.B.O. 114), and participated in an informal hearing (E.B.R.M. 80) arising from a matter referred to the Board by the Minister of Natural Resources under Section 11 of the Petroleum Resources Act.

E.B.O. 111 dealt with an application by G.W. Clarke Oil and Gas Company for an Order requiring and regulating the joining of interests, generally referred to as unitization, within the Enniskillen #26 Pool located in Enniskillen Township, Lambton County, for the purpose of gas production, the designation of management, and the determination of the lessees with a working interest in the pool as well as apportioning the costs and benefits of operating the pool. After the filing of the Applicant's prefiled evidence in October 1984, the Petroleum Resources Section was asked by Board staff to examine the Applicant's evidence and to provide expert testimony at the hearing. The main point of contention concerned the location of the pool boundaries which in turn delimits the boundaries of the participating and non-participating areas with respect to both working interest (lessee) and royalty interest (lessor) parties. At stake was the Applicant's estimate of 10.2 to 14.2 $10^6 m^3$ of gas worth about $1.4 to $1.7 million.

The hearing was held in Sarnia, Ontario, from March 5 to March 8, 1985. Six witnesses testified on behalf of the Applicant; R.A. Trevail and P.A. Palonen of the Petroleum Resources Section testified on behalf of Board staff; and two additional witnesses were called by various intervenors. Four landowners made oral submissions on their own behalf.

The issues addressed by the Board in its Reasons for Decision included the boundary of the participating area, boundary of the unit area, parties to the unitization, landowner compensation, and gas company compensation. The Board adopted the boundaries of the participating area based on the zero contour of the net pay isopach as interpreted by R.A. Trevail from available geological evidence. Board members also accepted the location of unit area boundaries as proposed by Ontario Ministry of Natural Resources staff as well as the determination of division of royalties among landowners and the working interest of the companies involved

As for landowner compensation, the Board set royalty payments for gas at 6.25%, the value proposed by the Applicant, to be shared on acreage basis. Payment to landowners for acres lying outside the participating area but within the unit area was set

at $15.00 per acre per year. Land contiguous to the unit area was eligible for payment of $10.00 per acre per year.

The Board determined that Union Gas Limited was not eligible for compensation under the Joint Operating Agreement as Union Gas Limited had produced gas from the pool for a number of years without compensation to the other parties. However, the Board did order that costs accrued by G.W. Clarke Oil and Gas Company be repaid under the Joint Operating Agreement after royalty payments are determined and paid, but before working interest payments.

At the formal hearing for E.B.O. 114, technical advice was provided to Board counsel by P.A. Palonen and H.E. Habib. Once again, the Board was concerned with an application for an Order requiring and regulating the joining of interests, this time within the Cromar Pool located in Moore Township, Lambton County.

The applicant, Ram Petroleums Limited of Toronto, contended that the Cromar Pool, consisting of one producing gas well, one shut-in gas well, and two oil wells was a single, relatively large reservoir of oil underlying a substantial volume of gas.

The intervenors, Forbes Resources Incorporated, H. Brett Associates Limited (together referred to as Forbes/Brett), and B. Corden, however, strongly opposed Ram Petroleums Limited's interpretation testifying that in fact there were two separate and distinct hydrocarbon pools, one gas and one oil.

Following a rather lengthy hearing, April 29 to May 1 in Sarnia, and May 14 to May 17 in Toronto, the Board spent three months reviewing evidence presented and written argument received from the parties involved. In September, the Board released its Reasons for Decision finding in favour of the two-pool concept and ordering unitization of the pool containing the two gas wells (Cromar East). The parties were given 30 days to reach an agreement with respect to the pool boundaries. If agreement was not reached within the allotted time period, the Board recommended that the producing gas well be shut in until such time as agreement is reached or the Board settles the issue by Order. Agreement was not reached within the alloted 30 days and the well was subsequently shut on October 16, 1985. At the time of writing, the well remains shut in. In addition, Forbes/Brett was designated operator of the pool based on 15 years experience in the area.

Persuant to Section 11 of the Petroleum Resources Act, the Minister of Natural Resources refers to the Board for a report any application to inject fluids into a geological formation where the point of injection lies within 1.6 km of the boundary a designated natural gas storage area. The Board in turn holds a hearing, then reports its findings to the Minister. E.B.R.M. 80 concerned an application made by Proto Resources and Associates to inject fluid into the Silurian Guelph Formation by way of a procedure known as acid fracturing utilizing 9.09 m^3 of 28% HCl. The objective of acid fracturing is to increase the natural porosity and permeability of the formation in the vicinity of the wellbore, thereby increasing the drainage surface area open to the wellbore. This procedure generally results in increased rates of production and is considered to be proper oil field practice.

Natural gas storage reservoirs are a very valuable asset to the Province and it is important that their integrity remain intact. Therefore, any procedure undertaken within the 1.6 km buffer zone, such as acid injection, which may potentially cause irreparable damage to the gas storage reservoir, should have certain limiting operating conditions placed on it so that such damage does not occur. P.A. Palonen and R.A. Trevail supported this viewpoint at the hearing held in Toronto, November 14, 1985.

In its report to the Minister, the Board recommended that a permit to inject HCl acid into the Guelph Formation be subject to the following conditions:

1. Maximum bottom hole pressure: 11 030 kPa
2. Maximum injection rate: 0.79 m^3/minute
3. Maximum volume injected: 9.09 m^3
4. The complete procedure to be witnessed by a representative of the Petroleum Resources Section and Union Gas Limited.

The Board also expressed concern as to whether the 1.6 km buffer zone is realistic or not. It recommended the Petroleum Resources Section undertake an appropriate study to determine whether data exists or can be developed, either by reference to actual experience or by simulation, to support the assumption that a 1.6 km buffer zone provides adequate protection from damage by the procedure of formation fracturing.

Geoscience Information

"Oil and Gas Developments in Eastern Canada in 1984" (Trevail and Parker 1985) was compiled and written for the American Association of Petroleum Geologists. This annual report summarizes activities and highlights of exploration and production trends in Ontario and Eastern Canada for 1984. Reprints are available at the Petroleum Resources Laboratory.

R.A. Trevail presented one technical paper and co-authored three other papers presented in 1985. "Tectonic and Diagenetic Controls on the Development of Middle Ordovician Carbonate Hydrocarbon Reservoirs, Essex County, Ontario" (Trevail, in press) was presented at the 24th Annual Conference of the Ontario Petroleum Institute held in London, Ontario. Recent oil discoveries in the Middle Ordovician Trenton and Black River Groups have stimulated exploration for deep targets in the region and identified a need to understand more fully the tectonic and diagenetic controls on the genesis of these fracture related reservoirs.

Essex County was chosen as the area of investigation as 7 of the 20 known Ordovician pools are located within its boundaries. Detailed study of the regional geology and reservoirs themselves utilizing XRD, SEM, XRF, and microprobe analyses confirmed the previously held view that fracturing, dolomitization, and hydrocarbon entrapment are intimately associated.

Reservoir porosity is generally confined to dolomitized bioclastic zones of the Verulam and Kirkfield Formations and dolomitized burrows of the Gull River Formation with minor development in the fracture zone. Porosity types include intercrystalline, interparticle, intraparticle, vug, channel, and fracture.

Minor occurrences of sphalerite, barite, and sulphide mineralization containing copper and nickel are associated with the dolomitized fracture zones and reservoirs. Such minerals are typically associated with Mississippi Valley Type (MVT) lead-zinc deposits.

Besides mineralization, other features the reservoirs have in common with MVT deposits include dolomitization of host rock, development of baroque (sparry) dolomite, linear fracture zones, and evidence of subaerial exposure (karstification).

It is proposed that during lithification, structural deformation related to rejuvenation of a Precambrian fracture framework, triggered by orogenic events in the nearby Appalachian Orogen, created vertical fractures in the carbonate rock. Such fractures served as conduits for diagenetic fluids which dolomitized the host rock, created porosity, and deposited minerals typical of MVT deposits. Oil derived from the Collingwood Member of the Cobourg (Lindsay) Formation migrated into the host reservoirs sometime following the Mississippian.

Also presented at the 1985 Ontario Petroleum Institute Conference were "The Use of Remote Sensing Technology in the Search for Oil and Gas in Southern Ontario" (Singhroy and Trevail, in press) and "Computer Innovations in the Petroleum Resources Section—OPDS" (Hesselmans and Trevail, in press). The former dealt with identifying lineaments utilizing enhanced LANDSAT MSS and thematic mapper (TM) images as well as airborne colour infrared and thermal infrared data. Also discussed were difficulties in differentiating structural lineaments from other types of lineaments in an area of thick glacial drift and intense agricultural activity. The latter paper, presented by C. Hesselmans, Acting Systems Analyst, described the design, implementation, and capabilities of the Ontario Petroleum Data System (OPDS). OPDS is a computerized system for acquisition, storage, retrieval, and processing of oil and gas well data installed on a DEC VAX 11/780 computer accessible by a IBM PC-XT and/or remote terminal such as the DEC VT220.

In October, M.T. Holroyd, Vice-President, Research and Development, DataPlotting Services, Incorporated presented "OPDS: The Ontario Petroleum Data System" (Holroyd and Trevail 1985) at the 55th Annual International Meeting and Exposition of the Society of Exploration Geophysicists held in Washington, D.C. Topics discussed included hierarchal database structure, data input and verification, transfer files, and central site operations on a VAX 11/780 including main database maintenance (backups, error recovery, etc.), large volume data loading and retrieval, large scale applications processes, and high precision, high quality graphics output.

Statistics and Highlights

As the 1984 Report of Activities (Feenstra *et al.* 1985) contained statistics up to and including November 30, 1984, the authors feel the reader would be well served if the final 1984 results were presented herein. The 200 wells drilled in 1984 were divided among 71 exploratory, 101 development, and 28 service wells. The drilling success rate was 50% with 54 wells completed as gas producers (11 exploratory, 43 development) and 26 wells completed as oil producers (9 exploratory, 17 development). A total of 97 158 m of section was drilled. Both oil and gas production increased in 1984 with total production of 90 376 m^3 of oil and 548 166 x 10^3m^3 of natural gas. Further details are available in Trevail and Parker (1985).

Drilling and production statistics are available for the period up to and including November 30, 1985. Table 15.1 provides a summary of wells drilled, listed by county and township. Petroleum activity highlights are shown in Figure 15.1.

Statistics indicate land based drilling is down 7% from 1984, divided among 47 exploratory, 34 development, and 22 service wells drilled. A total of 58 862.6 m was drilled. The success rate for exploratory drilling was 23% with 3 oil producers, 8 gas producers, and 33 dry holes drilled. Three exploratory wells were listed as suspended. Development drilling was 77% successful resulting in 22 oil producers, 4 gas producers, and 8 dry holes.

A total of 71 wells were drilled offshore in Lake Erie in 1985. Forty-two were completed as gas producers for an overall drilling success rate of 59%. A total of 37 790.8 m was drilled offshore.

Oil production to the end of November was 103 184.7 m^3. Projected estimates of 1985 oil production exceed 112 000 m^3, a 24% increase over 1984. The increase in production is attributed to the Mersea 1-15-B and Dover 7-5-V oil pools coming on full production during the latter half of the year. Natural gas production in 1985 is estimated at 535 000 10^3m^3, a slight decrease from 1984.

The Consumers' Gas Company Limited, in conjunction with partners Onexco Oil and Gas Limited, and Pembina Resources Limited continued development of the Mersea 1-15-B pool. At the present time, ten wells are on production and two other oil producers are awaiting hook up. The Dover 7-5-V pool, operated by E.P. Rowe Oil Limited and Ram Petroleums Limited, currently has four producing oil wells, two suspended oil wells, one shut in gas well, and one well awaiting completion. Both of these pools produce hydrocarbons from the Middle Ordovician Trenton and Black River Groups. Together, the two pools now account for 44% of Ontario's daily oil production of 360 m^3 per day. The percentage is expected to increase once the shut in and suspended wells are put on production.

Devran Petroleum Limited of London, Ontario, began developing and implementing a mine-assisted gravity drainage of petroleum project in the abandoned Sarnia-London Road Pool in Sarnia Township, Lambton County, to recover a large percentage of the estimated 2.1 10^6m^3 of oil remaining in place. Shell

Canada Resources Limited is sharing the costs of the $6.3 million project on a roughly 50/50 basis. Plans called for sinking a vertical mine shaft into the oil-bearing horizon at 120 m and, from two work stations excavated at the bottom of the shaft, drill horizontal holes into the pay zone. A radial pattern of 24 drill-holes (one every 15°), 760 m in length is expected to drain an area of approximately 160 ha. Over 18 000 horizontal metres of open hole will be drilled in each pay zone resulting in over 40 times the amount of reservoir exposure normally available in conventional vertical well recovery techniques.

The initial phase of shaft excavation was completed in March with 2.7 m casing set into bedrock at 33 m and cemented in place. Site work and erection of surface facilities were carried out through the Summer. In early September, Patrick Harrison of North Bay, the mining contractor, arrived at the site.

The second stage of excavation, through approximately 85 to 90 m of Devonian shales and carbonates, commenced in late November with completion targeted for mid-January. Construction of production stations is scheduled to be finished one month later. Devran Petroleum Limited officials expect horizontal drilling to begin in early March. Anticipated initial production rates range from 16 to 80 m^3 per day. A large number of companies from outside the Province, both Canadian and American, have expressed interest in conducting hydrocarbon exploration programs in Ontario, a reversal in the trend of exploration capital leaving the Province following introduction of the National Energy Program (NEP) in 1980. Shallow drilling depths, relatively low drilling and completion costs, local markets, and recent successes are attractive incentives to out-of-Province investors.

MINERAL RESOURCES ACTIVITIES

The primary objective of the mineral resources program in Southwestern Region is to stimulate exploration and development of industrial mineral resources in the region. The program provides information and professional advice regarding local and regional geology, mineral deposits, exploration, mining, mineral processing, uses, and markets.

Current extraction from Paleozoic limestone, dolostone, and shale, and Quaternary sand, gravel, and clay deposits at pits and quarries is for construction aggregate, lime for iron, steel, and soda ash, grey and white cement, porous clay drain pipe, and building stone markets. Total production is expected to show a modest increase over the 1984 level of 22

million tonnes at 562 licenced and 110 wayside pits and quarries (Table 15.2), and with an estimated value of $70 million.

Current extraction of salt at 2 underground mines and 42 brine wells in the various Salina Formation salt units is primarily for de-icing, chemical (caustic soda, chlorine, soda ash), and foodgrade markets. Based on company estimates, total production declined below the 1984 level to 6.1 million tonnes valued at $130 million. This decline in production is mainly due to a labour strike at one of the rock salt mines.

The following are some of the new developments in Southwestern Region:

- startup of mosaic wall tile manufacture at the large, new, ultra-modern plant of Windsor Ceramic Tile Canada Limited;
- startup of large flower pot and giftware manufacture at the new plant of Castle Ceramics Limited in Norwich;
- extension of natural gas pipeline to the Parkhill plant of Martin Clay Products enabling the company to fire its kilns more efficiently for clayware manufacture competitive with plastic pipe;
- export of clay flue lining to U.S. markets for the first time by Canada Vitrified Products of St. Thomas, the sole Ontario manufacturer of clay flue lining and sewer pipe;
- specification of Adair Marble for the new Canadian Embassy in Washington;
- startup of new Bruce Marble and Stone quarry and 'dressing' operation in the Bruce Peninsula; and
- startup of new Burnes Pierce Quarry operation on Pelee Island ending importation of construction aggregates from Ohio.

The following are some of the new exploration and development activities planned for 1986 in Southwestern Region:

- startup of new Sutherland Construction Limited quarry operation for construction aggregates north of Owen Sound;
- exploration for new sources of construction aggregates in the London-Sarnia, Markdale-Meaford, and Owen Sound-Kincardine areas;
- assessment of the potential for concrete aggregates from the Lucas Formation in the Windsor-Leamington area;
- exploration of Kettle Point Formation shale as cement making raw material at a potential quarry site in the London-Sarnia area to facilitate planned changeover from wet to dry-processing at the Woodstock plant of Canada Cement Lafarge Limited;
- use of Arkona Formation shale and other local clays and shales in testing and manufacture of vitrified clay products replacing imported raw materials;
- assessment of the inactive Dresden Tile plant and clay deposit for brick manufacturing;

- exploration and testing of kaolinitic Bedford Formation shale;
- assessment of building stone potential using ground radar surveying techniques;
- exploration of Formosa Reef limestone at several deposits in the Wingham-Walkerton area as potential raw material for the glass industry; and,
- exploration of dune sands at several properties in the Grand Bend area as potential raw material for insulating fibre glass.

The following sections summarize for each commodity the mining, manufacturing, and exploration activities by industry, and pertinent activities by the Ontario Geological Survey and Southwestern Region. Region's activities include property examinations and area specific resource inventory and assessment projects as a means of stimulating new exploration and development, as well as providing effective input to resource planning and conducting or participating in displays, field trips, and workshops as a means of resource promotion.

Construction Aggregates

While sand and gravel aggregate production at licenced pit deposits in Southwestern Region in 1984 remained at the same level as during the previous year (14 million tonnes), wayside production (2.7 million tonnes) was up by 20% in response to growing highway construction needs.

Quarry production of crushed stone aggregates for construction purposes (2 million tonnes) increased across the Region, notably at Amherst Quarries Limited and Kennette Contracting Company Limited operating along with Allied Chemical in the Lucas Formation at the McGregor Quarry, southeast of Windsor, in the Chatham District (Figure 15.2a). This area has traditionally not been able to meet its needs in production of asphalt, concrete, and Granular A aggregates.

More than 2 million tonnes of crushed aggregates are imported annually from Komoka area pits southwest of London (South Winds Sand and Gravel), quarries in northern Michigan, and the Manitoulin Dolomite Incorporated quarry on Manitoulin Island. Docking facilities for unloading aggregates shipped from U.S. sources and Manitoulin Island exist at Point Edward (Sarnia), Courtright, Sombra, Windsor, and Kingsville. Aggregates from Komoka area sources are trucked to Lambton County and some of the nearer townships in Kent and Essex to supply growing specialty market needs.

The Burnes Pierce Quarry on Pelee Island started operating to supply crushed stone aggregates from Dundee Formation limestone for local construction needs replacing aggregates imported from Ohio. It is the only active quarry on the island.

Harold Sutherland Construction Limited plans to operate a new 200 000 tonnes per year crushed stone quarry in Amabel Formation dolostone located in the Niagara Escarpment area of Grey County, north of Owen Sound. The numerous plan review hearings, however, are becoming rather cost-prohibitive.

Accompanied by staff consulting to a major construction aggregate producer in the Region, several abandoned and operating pits and quarries, and other selected outcrops of granular and bedrock aggregate resource materials in the London-Lake Huron area were examined as a means of encouraging effective exploration and development of a new pit or quarry deposit in the area. Exploration at several selected sites will begin in 1986.

Together with staff consulting to a major aggregate producer from outside the Region, outcrops of Amabel Formation dolostone, located north of Markdale and away from the Niagara Escarpment Plan area were examined as a means of encouraging effective exploration and development of a new construction aggregate quarry operation. Exploration at one available property will commence in 1986.

Drill core samples from the lower part of the 30 to 35 m thick Dundee Formation limestone at Devran Petroleum Limited's proposed oil mining site near Sarnia (Figure 15.2b) were brought to the Ministry of Transportation and Communications for testing and assessment of construction aggregate potential. Preliminary results suggest suitability of the lower Dundee limestone at this site for granular base, subbase, and crushed maintenance materials. Sampling of the entire limestone sequence including the hard, dense central zone will commence in January 1986, when sinking of the shaft through the Dundee Formation at depths of 100 to 135 m takes place.

Southwestern Region's inventories and assessment of sand and gravel aggregate resources in deposits presently licenced under the Pits and Quarries Act have been carried out annually since 1983. These studies are intended to supplement ongoing inventories and assessments by the Aggregate Assessment Office of the Ontario Geological Survey which do not provide specific resource data on licenced commercial sources. Such information is critical for assessing present and short-term supplies of construction aggregate resources at the local level for effective input to the municipal land use planning process. The reports include information on geological descriptions, sampling, and estimates of the quantity and quality of remaining sand and gravel aggregate resources in the licenced sources. Laboratory analysis of the samples to determine grain size distribution, soundness, absorption, and lithology (petrographic number) are performed by the Materials Testing Laboratories of the Ministry of Transportation and Communications. Results of these projects are now complete for the Chatham, Wingham, and Owen Sound Districts. In 1985, W.R. Cowan of Palliser Environmental and Terrain Services Incorporated completed field studies in the Komoka, Byron, Fanshawe, and Simcoe areas. Studies will be continued in 1986 in the Aylmer District. Results of the projects are incorporated in Aggregate Resources Inventory Papers published by the Ontario Geological Survey and are made available to municipalities for land use planning purposes. A property report detailing the results is made available to each respective owner/operator. The Ministry of Transportation and Communications uses results of the studies for detailed assessment of new concrete fine and coarse aggregate potential in Southwestern Region.

Pit operations in Yarmouth Township are the chief producers of sand and gravel construction aggregates in Elgin County. These operations have ample supplies of sand but very limited workable amounts of gravel. A new area with high gravel potential, however, has been delineated on the basis of field studies in the Sparta Moraine area southeast of St. Thomas. (The Sparta Moraine is shown on Map P.2827; Dreimanis and Barnett 1985.) Field work was initiated in 1984, completed in 1985, and consisted of examination of buried sand and gravel at 15 pits, 26 hammer seismic refraction survey lines, 14 small diameter power auger holes, 7 large diameter power auger holes, and sampling. Samples were tested for potential aggregate quality by the Ministry of Transportation and Communications. Results of this project have been summarized in a Resources Report which can be obtained from the Petroleum Resources Laboratory and Aylmer District office. Results of this study will also be incorporated in the Aggregate Assessment Office report on Yarmouth Township to be published in 1986 by the Ontario Geological Survey.

Essex County has, aside from the upper lift in the upper part of the Lucas Formation (Anderdon Member) at Allied Chemical's McGregor Quarry, no known workable deposits suitable for the production of crushed aggregates of very high quality suitable for all aggregate uses including concrete structures and pavements (Koniuszy and Katona 1981). Crushed stone from this upper lift, however, is primarily used in making lime. A joint project by the Southwestern Region offices of the Ministry of Transportation and Communications and the Ministry of Natural Resources was initiated in 1985 to assess new potential of the Lucas Formation for high quality crushed aggregates in the McGregor-Leamington area. In December of 1985, the formation was drilled and cored (76 mm diameter) at the following three sites with relatively thin glacial drift overburden (7 to 18 m): one north of Leamington, another north of Harrow, and the third south of McGregor. Cores will be slabbed at the Petroleum Resources Laboratory and the Ministry of Transportation and Communications will perform aggregate quality testing of core samples in 1986.

Staff of the Aggregate Assessment Office of the Ontario Geological Survey completed field studies of aggregate resource potential in the following seven townships in Southwestern Region: Orford in Kent County; Adelaide and Metcalfe in Middlesex County; Hibbert and Wallace in Perth County; West Wawanosh in Huron County; and Amabel in Bruce County. Brief summaries of important findings during the field work in the above townships are presented by Gorman and Szoke (1985).

During 1985, the Ontario Geological Survey published the results of aggregate resource inventories of the following seven townships in the Region: Holland (ARIP 100), Sullivan (ARIP 101), Derby (ARIP 112), Sydenham (ARIP 118), and Keppel and Sarawak (ARIP 119) in Grey County; and Hullett (OFR 5552) in Huron County.

Lime

In the Beachville-Ingersoll 'lime valley' area, BeachviLime Limited (Dofasco) acquired Domtar's lime plant, pulverized stone plant, and quarry operations. The combined 1984 production of crushed high-calcium limestone from the Lucas Formation for calcining and mainly captive supply to the iron and steel industry from the BeachviLime Limited and Stelco Incorporated operations (1.6 million tonnes) represents approximately 74% of the total production in the Region for all lime markets and was 20% lower than during the previous year.

Allied Chemical Canada Limited continues to increase production of +25 mm (1 inch) screenings of crushed high-calcium limestone obtained from the 10 m high upper lift (Anderdon Member, Lucas Formation) at its McGregor Quarry. At the Amherstburg plant, the limestone screenings are calcined (quicklime, CO_2) and with ammoniated salt-in-brine used in the manufacture of soda ash and by-product calcium chloride by the Solvay process. Soda ash is used in the manufacture of glass (second largest fraction in the glass batch), detergents, pulp and paper, and other chemicals. Soda ash is also used in water and sewage treatment, mining, and textiles. Calcium chloride is used in road construction and maintenance, for dust control in the summer, and for de-icing in the winter as a substitute for rock salt when corrosion is a major concern or as liquid calcium chloride treated rock salt to reduce rock salt application. Fluorspar obtained from sources outside the Region is used in the manufacture of hydrofluoric acid, by-product gypsum, and other chemicals.

Grey Cement

The total 1984 production of local limestone and clay aggregates for grey cement manufacturing in the Region remained at the 1983 level of approximately 1 million tonnes.

The Woodstock plant of Canada Cement LaFarge Limited currently produces at 60% capacity. Quarrying activity has been extended downward through 29 m of high-calcium limestone (Lucas Formation) and 15 m of cherty limestone (Amherstburg Formation) to near the contact with the very siliceous limestone of the Bois Blanc Formation. New sources of dry shale are required to facilitate a planned changeover from wet to dry-processing of the raw materials. Since the plant also manufactures special types of cement, no winter shutdown is anticipated. The company plans to purchase at least 15 terminals in the Great Lakes area.

To optimize production of multiple types of cement at its Woodstock plant, Canada Cement Lafarge Limited completed 1372 m of diamond drilling (19 holes) through the Lucas, Amherstburg, and Bois Blanc Formations and into the Bass Islands Formation at the quarry site. Cores were split and sampled for chemical analysis. Split core from one hole, representative of the entire 80 m thick sequence, is stored at the Petroleum Resources Laboratory. The company also sampled the complex glacial drift overburden at the quarry for chemical analysis and shales and glacial lake clays at several pits and other outcrops scattered across the southern part of the Region. company plans to complete 10 shallow diamond-drill holes in January 1986 on a property in the London-Sarnia area to further evaluate the quartz- and organic-rich Kettle Point Formation shale as raw material for cement manufacture.

The St. Mary's Cement Company plant in St. Mary's resumed operation in May 1985 after a five-month shutdown. Its quarry produces crushed limestone (Dundee and Lucas Formations) and glacial clay aggregates for dry-mixing. Sales of cement are currently very good, and there will not be a scheduled winter shutdown for the first time in three years. New U.S. sales of cement and clinker have resulted from the opening of a new terminal and purchase of the Peerless cement plant in Detroit.

White Cement

The Woodstock plant of Federal White Cement is the largest white cement producer with 45% of the total annual production in North America. The dry-process plant uses a raw mix, 80% of which is composed of crushed high-calcium limestone (Lucas Formation) obtained from local lime producers in the Beachville-Ingersoll 'lime valley' area, and 20% of which is composed of imported silica fines, kaolin clay and high-reflectance gypsum and anhydrite.

Clay Products

In 1985, extraction of local clay and shale in the Region by the structural clay products industry is at four remaining plants exclusively for the manufacture of porous clay drain pipes. Martin Clay Products remains a strong leader in a declining industry researching new applications.

Other plants in the Region still import clays for the manufacture of vitrified structural clay products, ceramic tile, and pottery. Canada Vitrified Products is currently the sole Ontario manufacturer of vitrified clay chimney flue linings and sewer pipes. Replacement of costly long-haul transported clays by cheaper local sources will be necessary for the company to remain competitive.

The Region witnessed start-up production at two new plants: one for the manufacture of mosaic wall tile and other ceramic tile products at Windsor Ceramic Tile Canada Limited and the other for the manufacture of large flower pots and giftware at Castle Ceramics Limited in Norwich. Products from both plants are destined mainly for export markets in the U.S. Both plants combined will have created more than 200 new jobs when fully operational.

Barringer Research Limited of Rexdale measured 28% kaolinite in shale from the Lower Mississippian Bedford Formation. The sample is from a well drilled in 1965 in Moore Township, Lambton County. Clay mineral analysis for correlation purposes was performed on selected clay and shale samples obtained from Southwestern Region using the newly developed reflectance radiometry method ('Claypak' field method). Duplicate Bedford shale samples have been forwarded to the Geoscience Laboratories of the Ontario Geological Survey, Toronto, and the University of Waterloo for confirmation of the identification of kaolinite by conventional clay mineralogy techniques. Kaolinite has previously not been positively identified in clays or shales of southwestern Ontario. Kaolinitic clays and shales are extensively used in the manufacture of vitrified clay products.

Porous Clay Drain Pipe

Porous clay drain pipe manufacturing in Ontario has declined drastically from 86% of all drain pipe produced in the 1960s to <12% today due to markets lost to plastic pipe and lack of research and development. Manufacturing plants and nearby clay or shale 'pits' are concentrated in southwestern Ontario, the agricultural heartland of the Province, and specifically in Southwestern Region. This industry numbered 20 active plants in the Region during the 1960s; however, only 6 plants were active in 1984, providing employment for 85 people. These plants consumed a combined total of slightly more than 38 000 tonnes of clay and shale (10.5 million drain pipes), a rather small amount considering usage in brick or cement manufacturing. The combined total of local glacial lake clays extracted by Dresden Tile Yard (1981) Limited, Norwich Brick and Tile Yard (1979), and Paisley Brick and Tile Company Limited stood at the same level as in 1983 (12 540 tonnes). The combined total of Arkona Formation shale extracted by Martin Clay Products (Amos C. Martin Limited, Parkhill), and George Coultis and Son Limited at Hungry Hollow and Thedford, respectively, and Meaford-Dundas or Georgian Bay Formation shale extracted by Meaford Tile Limited increased by 18% over the 1983 level to 25 760 tonnes. This rise is entirely due to increased production at Martin Clay Products making it the leading producer of clay drain pipe. The usage of local clay and shale in drain pipe manufacturing in the Region is expected to decline in 1985 with the closure of the Dresden Tile and Meaford Tile plants and inactivity at the George Coultis and Son plant. Shale of the Arkona Formation, however, may see further use in the near future as raw material for pottery, flue lining, and sewer pipe manufacture in the Region, replacing costly imported clays and shales.

Martin Clay Products (Amos C. Martin Limited) manufactures porous clay drain pipe at two plants: one in Parkhill to service southwestern Ontario and another in Wallenstein to service mid-western Ontario. The company works two 'clay pits': one in more clayey shale of the Arkona Formation at Hungry Hollow near Arkona for raw material feed to both plants, and another at Georgetown in more silty Queenston Formation shale to service the Wallenstein plant. Completion in 1985 of a new pipeline facilitated the conversion from oil to more efficient natural gas firing of the kilns at the Parkhill plant. In 1985, Martin Clay Products also started manufacture of thinner-walled and smaller 3.5 inch (89 mm) diameter drain pipe to be competitive with 4 inch (102 mm) diameter plastic pipe. The company recently received a federal grant towards research on beneficiation of its 'clays' for the manufacture of new products (brick, floor tile, vitrified pipe) at both plants. Martin Clay Products is currently conducting trials with a faster drying-firing-cooling cycle for its clayware.

To assess potential of the entire Arkona Formation shale sequence as raw material at both Hungry Hollow north and south quarry sites, and to assist in quarry planning, Martin Clay Products cored one hole through 34.5 m of dry Arkona shale and 3 m of underlying Rockport Quarry Formation limestone near the type section of the Hungry Hollow Formation. The hole was drilled in the south quarry, the floor of which lies 9 m below the exposed contact between Arkona Formation shale and the overlying Hungry Hollow Formation limestone. Only the 9 m of shale below the quarry floor is similar to the top 9 m, i.e. grey clay shale with a few thin fossil bands. The remainder of the shale sequence contains frequent, thin, hard, calcareous interbeds of fossil hash and bioclastic mudstone. Slabbed, 76 mm (3 inch) diameter core of the entire sequence is stored at the Petroleum Resources Laboratory.

Dresden Tile Yard (1981) Limited closed its clay workings in September 1985 and is currently for sale. New interest in buying the plant and licenced pit deposit has already been expressed by the largest brick manufacturer in Italy during a recent visit by its staff and Toronto-based consultants. Samples of the clay deposit have been taken back to Italy for testing.

Vitrified Clay Flue Lining and Sewer Pipe

Canada Vitrified Products Division of National Sewer Pipe (NSP) Limited in St. Thomas is, since the closure of both NSP plants in Clarkson and Hamilton, currently the sole Ontario manufacturer of vitrified clay chimney flue linings, offsets, chimney tops, and vitrified clay sewer pipes, fittings, and accessories including rubber couplings. The company also manufactures vitrified clay products for specific agricultural and architectural purposes. The St. Thomas plant was originally established in 1934 to utilize imported clays from Pennsylvania shipped across Lake Erie to Port Stanley. Shale raw materials are presently trucked in from NSP's Queenston Formation deposit at Burlington and from a deposit of upper Devonian Machias shale in northwestern New York. Minor amounts of pulverized dolomite to control absorption in the clayware are trucked in from Hamilton. The sewer pipe greenware is fired in a shuttle kiln with 36 gas-burners providing even temperature distribution; flue lining greenware is fired in round, more efficient pressure-fired, downdraft periodic kilns. Both products are mainly for Ontario markets in residential and industrial construction; however, the company entered U.S. flue lining markets for the first time in 1985 and sales accounted for 25% of the total.

Canada Vitrified Products also began pre-production trials in 1985 of flue lining made from blends composed of shales of Queenston and Arkona Formations to replace costly imported New York shale. The company plans to try similar blends for sewer pipe manufacture. Clay sewer pipe was once widely used; however, PVC is now mainly used in smaller diameter markets and concrete pipe in larger diameter applications. Clay sewer pipe with superior acid resistance properties is still specified when corrosive chemicals will be passing through the drainage system; however, it may not be available locally. The company is currently also assessing new markets such as special brick, structural tile, and roofing tile. To remain competitive in clayware manufacture, it is essential for the St. Thomas plant to find suitable local clays such as those of the Arkona Formation to replace more costly distant sources.

New Start-Ups in Ceramics

Windsor Ceramic Tile Canada Limited, affiliated with U.S. Ceramic Tile Company of East Sparta, Ohio, started operation of a large, new, ultramodern ceramic tile plant including a mini-factory research and development centre in 1985 at Ojibway Park in Windsor. U.S. Ceramic Tile Company operates four plants in the U.S., two in Ohio, and one each in Mississippi and Pennsylvania. The Windsor plant equipment was designed, manufactured, and installed by Riedhammer Industrieofenbau Gesellschaft of Nurnberg, West Germany. The manufacturing process includes body preparation by wet mixing of proportioned quantities of clay and shale, slip preparation by wet grinding of body mix in ball mills, mixing of additives such as nepheline syenite at agitator tanks, pumping of body slip to slip arcs for storage, pumping of body slip to spray dryer where spraying of the slip through turbulent superheated air yields a pressable, granular material with 8% or less moisture, shaping of the flat greenware tiles by hydraulic dry-pressing, glazing, and biscuit firing at 1230°C of the greenware using a single layer fast-firing process in three sled-type, gas fired tunnel kilns each with 2787 m^2 (30 000 square feet) of tile per day capacity. The clay body consists of Pennsylvanian-age clay and shale imported from the Tuscarawas Valley area in northeastern Ohio. The clay material is a grey to buff firing, carbonate-free, low plastic, silty underclay composed mainly of kaolinite, illite, and quartz. The shale material is a red firing, carbonate-free, silty shale with abundant illite and quartz, and minor kaolinite. The company unsuccessfully tried using small quantities of local Essex County 'red top' clay in the body mix. Windsor Ceramic Tile Canada Limited is presently testing various Ontario and other Canadian clays. Nepheline syenite is supplied by an Ontario producer located outside the Region. Although targeted for start-up in March 1985, production did not begin until December due to production line modifications and a six-week strike at the plant. A two-line system is currently operative and the projected initial production level for 1986 is set at 1 million square metres (10 to 12 million square feet) of mosaic wall tile, i.e. more than Canada's entire production; it will increase further in 1986 when the third line is operative. Planned annual capacity of the Windsor plant is close to 3 million square metres of ceramic tile products, i.e. 25% of Canada's annual consumption, with 75% of the total shipments destined for U.S. markets and 25% for Canadian markets. At full capacity, the plant will provide 175 new jobs.

Castle Ceramics Limited started operation in 1985 of a new plant in Norwich for the manufacture of large flower pots and giftware using ball clays and feldspar imported from the U.S. The company imported plant equipment from The Netherlands and received a federal grant towards purchase of a new kiln and other equipment. Castle Ceramics Limited

will be one of the largest potteries in the Region creating 30 new jobs when fully operational. Products are mainly for export markets in the U.S. The company has shown interest in testing local clays.

A study of the geology and ceramic properties of selected clay and shale deposits in south-central and southwestern Ontario was undertaken by Martini and Kwong (1985) for the Ministry of Natural Resources. The objectives of this study are as follows:

1. to evaluate selected clay and shale samples and mixtures as suitable raw materials for manufacture of clay roofing tile and other vitrified products;
2. to relate variations in ceramic properties of vitrified products to the geology of the clay and shale deposits; and
3. to establish exploration and mining criteria for resources needed for potential long-term industrial development.

Selected clay and shale raw materials from Southwestern Region include non-calcareous to moderately calcareous, red firing samples from licenced pits as well as promising new deposits. The licenced extraction sites are in lower Georgian Bay or Dundas Formation shale at Meaford, upper Arkona Formation shale at Hungry Hollow, and glacial lake clay at Dresden. The potential new deposits are in upper Blue Mountain Formation shale at Camperdown, upper Cabot Head Formation shale at Pyette Hill north of Owen Sound, and modern Nanticoke Creek alluvial loam north of Nanticoke. The results of this study will provide a valuable preliminary assessment of new potentials for alternate products from Region's 'heavy clays', i.e. vitrified clay roofing tile, clay pipe, industrial floor brick, structural tile, and ceramic wall and floor tile. The study is progressing very well and results in the form of an Open File Report will be available early in 1986.

The objectives of another clay and shale study are to compile available information on the geology, ceramic properties, location and land use constraints, exploration, mining, processing, and present and potential uses of Southwestern Region's clay and shale resources, and information on additives such as aluminous waste materials. The six-week long project is sponsored by Martin Clay Products under provisions of Canada Works-Section 38: Ontario Mining Sector Work Program. The project is carried out by D.J. Ackersviller, J.A. Hyatt, and L.C. Walkom under general supervision of the mineral resources geologist. The results of this compilation will be available in the form of an Open File Report in 1986.

Building Stone

There are currently six active limestone building stone producers operating at seven quarries in Amabel Formation dolostones of the Owen Sound-Wiarton-Hope Bay area in the Bruce Peninsula. They are as follows: Adair Marble Quarries, Owen Sound Ledgerock Limited, Ebel Quarries, Bruce Marble and Stone, Cliff McCartney, and Don Ross (Figure 15.2a). Combined production rose from 23 000 to 30 000 tonnes during the period from 1976 to 1979, declined to 20 000 tonnes in 1981, and rose again to 32 000 tonnes in 1984 with estimated gross sales of $6.5 million. Production in 1985 increased at all quarry operations providing year-round employment for 50 people and seasonal employment for an additional 70.

Adair Marble Quarries (Division of Arriscraft Corporation) quarries blue-grey, thick-bedded Wiarton-Colpoy Bay Member dolostone, producing 8 to 12 tonne size mill blocks by drilling and broaching. The quarry has been deepened to 8 m. Mill blocks are trucked to the Company's finishing plant at Cambridge. At the plant, the mill blocks are first placed in inventory for 'seasoning', then cut into product blocks using circular diamond saws up to 2 m in diameter, and then cut into required thicknesses by a modified gang saw or 'multiple saw' using up to 16 blades simultaneously. Different finished surfaces are produced using sanding, thermal-finishing, bush-hammering, and polishing equipment. Finished products are marketed as Adair Marble and include sills, coping, coursing stone, paving stone, slabbing, and thin wall overlay. The company markets and distributes its products through a network of more than 270 dealers in North America. Adair Marble products account for 25% of total sales of the company including a broad range of uniquely manufactured calcium silicate masonry cladding products. The following are some of the notable applications of Adair Marble:

1. conference desk and credenza of the Prime Minister's office;
2. restoration of three Laurier Locks, Rideau Canal, Ottawa;
3. phase I and II restoration of the Old Port of Quebec, Pointe-à-Carey;
4. new Court of Justice building in Ottawa where Adair Marble thin overlay is bonded to concrete wall units providing an attractive concrete facing.

Adair Marble is also specified for the new Canadian Embassy in Washington.

Owen Sound Ledgerock Limited, Ebel Quarries, Bruce Marble and Stone, McCartney, and Ross quarry grey-brown, light grey to buff weathering, readily parting, thin-bedded Eramosa Member dolostones by hand quarrying techniques. Quarry depths currently vary between 2 and 4 m. Stone dressing is accomplished on site or at one of the neighbouring operations. Owen Sound Ledgerock Limited is planning to enlarge the licenced areas at its Owen Sound and Wiarton quarry sites. After two years of inactivity at the Clearstone Quarry Industries Incorporated site (former Rouse or Perfect Stone quarry) near Highway 6 north of Mar, Bruce Marble and Stone obtained a three-year lease and started operation in 1985. In addition to the Eramosa Member, the company also quarries and dresses stone obtained from the overlying, buff, fine-grained, thick-bedded Guelph Formation dolostone at this site.

Building stone quarries of Adair Marble Quarries, Bruce Marble and Stone, and Owen Sound Ledgerock Limited in the Bruce Peninsula were examined in the company of L.G.D. Thompson from the Tweed Office of the Ministry of Natural Resources to assess shallow subsurface geophysical techniques for detection of bedding spacing and variations, particularly those

related to biohermal development and reefal onlap respectively in Wiarton-Colpoy Bay and Eramosa Members of the Amabel Formation. Later, A-Cubed Incorporated of Mississauga carried out ground probing radar surveys for shallow subsurface (10 m) mapping of bedding features at one of the quarry sites. This method may be most economical for long and short term quarry planning and quality control.

The active quarry of Adair Marble at Hope Bay was visited in the company of Professor C.G. Winder and student Julian Kanarek of the University of Western Ontario to focus the latter's thesis study on pertinent geological parameters of the Amabel Formation at this building stone deposit.

A tour of the Bruce Peninsula building stone operations was conducted on October 8, 1985, in cooperation with the Ontario Association of Architects. The field trip was attended by 15 architects and several industry staff. All active quarry operations and processing facilities were visited including one private residence to demonstrate various stone applications. The tour was highly successful based on comments made by both building stone users and producers. Copies of the field trip guidebook are available at the Petroleum Resources Laboratory.

Southwestern Region geological staff conducted field inventories and assessments of potential dimension 'limestone' beds at past and present quarry operations excluding currently active building stone operations in the Bruce Peninsula. The most promising of all the potential dimension stone beds examined are the massive limestone layers in the Amherstburg and Pelee Island areas. At the Amherstburg quarry of Amherst Quarries Limited, blocks from several 2 m thick massive beds of limestone in upper and middle sections of the Lucas Formation have been recently 'dressed' by local stone masons for building uses. The building stone is very light grey, dense, and very fine grained or aphanitic in texture. The stone has been used in building of at least 20 homes in the Harrow area, the Windsor jailhouse extension, and for restoration of the McKenzie House in Windsor. Crushed stone quarrying activity at this operation is now at a minimum.

On Pelee Island, Dundee Formation bedrock is characterized by 1.5 to 3 m thick massive beds of buff or light grey fossiliferous limestone exposed at several licenced and abandoned quarry sites. Quarry blocks from this limestone formation were used in construction of the original Welland Canal locks. Applications of the building stone can be observed on and off the island in homes, churches, and other structures including breakwater armour stone hauled from licenced, but presently inactive, quarry operations. Mill blocks, which are 1.5 m thick, 4 m long, and more than 75 years old, can still be found at the abandoned William McCormick quarry on the island. Mill blocks from the same Dundee Formation limestone but then at the Anderdon quarry near Amherstburg were used in construction of, and still can be observed at, the lock chamber of the Sault Ste. Marie Canal which was completed more than 90 years ago. Applications of this building stone can also be seen at several historic buildings in Amherstburg. The Anderdon quarry is currently used for waste disposal.

Samples of these and several other promising dimension stone beds have been slabbed and polished, and are on display at the Petroleum Resources Laboratory together with photographs depicting various building stone applications. Sample cubes will be submitted for physical testing. Results of the project will be made available in 1986 in the form of a Resources Report on building stones of Southwestern Region.

Glass

The following three major glass plants are located in the Region:

1. Libby-St.Clair Incorporated in Wallaceburg manufactures container (beverage, storage) and specialty glassware (tableware);
2. PPG Canada Incorporated in Owen Sound manufactures flat glass for windows, windshields, doors, entire building curtain walls;
3. Fiberglass Canada Incorporated in Sarnia manufactures insulating (wool) fibre glass products for residential, commercial, and industrial applications.

The company's new research and development centre in Point Edward was officially opened in October 1985.

These glass plants use a wide variety of industrial minerals such as silica sand, soda ash, pulverized limestone, dolostone, nepheline syenite, salt cake, boron minerals, and colouring agents. Most of the minerals come from sources outside the Region except soda ash (Amherstburg), pulverized high-purity limestone (Beachville-Ingersoll area), and dolostone (Owen Sound).

E.C.King Contracting uses the -8 mm screening of Amabel Formation dolostone from its Sydenham Township quarry to produce sand-size aggregate at its Owen Sound Dolomite pulverizing plant for use in the manufacture of float-quality flat glass at the local PPG Canada Incorporated plant. By-product fines (Dolomite Filler #71,-180 microns) are used as aglime in northern Ontario and as filler in jointing compounds. Additional markets are sought for approximately 5000 tonnes.

Several relatively large eolian fine- to medium-grained sand deposits on properties operated by sand and gravel companies in the Grand Bend area (Pinery dunes) were examined for reported silica sand potential. Raw sand analysis by the Geoscience Laboratories of the Ontario Geological Survey, Toronto, suggests suitable gradation for insulating fibre glass manufacture but unsuitable mineralogical composition requiring removal of magnetic and carbonate minerals. Such benificiation may yield 50% recovery of a silica-feldspar concentrate of specified 'wool' fibre chemical composition.

Based on new interest by a glass manufacturing company, fossiliferous high-calcium Formosa Reef limestone of the Amherstburg Formation was sampled at five outcrops in the Wingham-Walkerton area for analysis of Co, Cr, Cu, Ni, and Mn by atomic absorp-

tion and ICP Spectrometer System methods at the Geoscience Laboratories, Ontario Geological Survey, Toronto. The measured concentrations in parts per million (ppm) are as follows: Co=<2; Cr=6-11; Cu=3-12; Ni=1-3; and Mn=42-70. These concentrations reflect perhaps the rich fauna present in the biohermal patch reef limestone. The concentrations of Cr, Cu, and Mn are relatively high considering requirements by the glass industry. Large drill core samples for further testing may be obtained by the company in 1986.

Natural Sands

Because of scarcity of information on natural sand deposits in Southwestern Region, samples of Quaternary sands from 40 different sites at licenced pits and other outcrops have been collected by regional geological staff for grain size, mineralogical and chemical analysis by the Geoscience Laboratories of the Ontario Geological Survey, Toronto. Twenty-eight samples of sand are from glaciofluvial and glaciolacustrine deposits, and twelve samples of sand are from eolian deposits scattered across the Region. Grain size of the samples falls basically into two groups: one consisting of fine- to medium-grained sand, and another consisting of coarse- to very coarse grained sand. In addition, six samples of silica sand from the Paleozoic Sylvania sandstone have been submitted to the Geoscience Laboratories, Ontario Geological Survey, Toronto, for mineralogical and chemical analysis. These samples are from wells drilled previously in Anderdon and Malden Townships, Essex County. Results of these and previous analyses of sands in the Region will be made available in 1986.

Industries in southern Ontario consume nearly 1 million tonnes of silica sand per year and none of it comes yet from the buried Sylvania sandstone in the Amherstburg area. Therefore, the objectives of another natural sand study are to compile and interpret available information on the geology, exploration, mining, processing, and market potential of silica sand from the Sylvania sandstone in Anderdon, Malden, North and South Colchester Townships, Essex County. This six-week long project is sponsored by McKean Quarries Limited (Sealey and Arnill Construction Limited) under provisions of Canada Works-Section 38: Ontario Mining Sector Program. The project is carried out at the Petroleum Resources Laboratory by D.J. Ackersviller, J.A. Hyatt, and L.C. Walkom under general supervision of the Mineral Resources Geologist. Results of this comprehensive study will be made available in the form of an Open File Report in 1986.

Rock Salt

A combined total of 4.5 million tonnes of rock salt was extracted during 1985 in Southwestern Region by underground mining methods. A modified room-and-pillar method is used in the 23 m thick Salina Formation A-2 Unit bed at a depth of 537 m at Domtar's Goderich Mine, and by conventional room-and-pillar design as employed in the 7.5 m thick Middle F Unit bed at a depth of 297 m at Canadian Salt's Ojibway Mine at Windsor. A production loss of one million tonnes at Goderich, due to a three-month strike during the summer, was only partly offset by an increase in production of 300 000 tonnes over the 1984 level at Windsor. Rock salt is primarily used in de-icing (80% to 85%), in chloralkali-manufacture (12% to 20%), and in minor miscellaneous markets including small-scale ion exchange water softening, and agricultural applications. Both companies export rock salt to the U.S.A.

Salt-in-Brine

Allied Chemical continued to extract salt using an underground solution method for on site industrial use from six wells into Salina Formation B Unit salt beds 30 m and 21 m thick at average depth of 335 m in the Amherstburg area. The company drilled two new wells for development into B Unit salt beds (Figure 15.1). Dow Chemical also continued to extract salt by brining for industrial use from 16 wells into B Unit and A-2 Unit salt beds 80 m and 37 m thick respectively at average depths of 740 m and 780 m in the Sarnia-Corunna area. The company drilled three new wells for development into the A-2 and B Unit salt beds. Total estimated production in 1985 by both companies (1.4 million tonnes) is 3% above the 1984 level. The extraction of salt by solution mining techniques by both companies is entirely for the industrial production of chloralkalis, i.e. chlorine and caustic soda at Dow Chemical and soda ash at Allied Chemical. Dow Chemical also manufactures hydrogen.

Fine Granular Vacuum Salt

The Canadian Salt Company Limited with 18 wells in production, and Domtar Incorporated with 2 wells in production, continue to extract B Unit salt brines from beds 30 m and 55 m thick respectively at depths varying between 427 m and 457 m in the Windsor and Goderich areas for the manufacture of evaporated, purified, fine granular vacuum salt products for open markets. Total estimated production in 1985 by both companies is 3% below the 1984 level. The extraction of salt brines by solution techniques followed by purification and vacuum-pan evaporation is mainly for food grade salt markets (60%), chemical industry (30% to 40%), and agricultural uses (10% to 20%).

ONTARIO GEOSCIENCE RESEARCH GRANTS

The following academic studies pertaining to Southwestern Region received Ontario Geoscience Research Grants for 1985-1986:

Grant 128: Subsurface Quaternary Stratigraphy Using Borehole Geophysics; R.N. Farvolden, J.P. Greenhouse, and P.F. Karrow, Department of Earth Sciences, University of Waterloo.

Grant 148: Geochemical Study of the Salina Group of Southern Ontario—Isotopes, and Major and Minor Elements; M.C. Miles, E.C. Appleyard, K. O'Shea, P. Lapcevic, S.K. Frape, and P. Fritz, Department of Earth Sciences, University of Waterloo.

Grant 205: Clay Mineralogy of Two Selected Carbonate Reservoirs in Southwestern Ontario; P.L. Chur-

cher and M.B. Dusseault, Department of Earth Sciences, University of Waterloo.

Grant 254: Exploration for Buried Aggregate by Remote Sensing Techniques; M.B. Dusseault, Department of Earth Sciences, University of Waterloo.

Grant 271: Effect of Grain Size on Calcining Properties of Carbonates; P.P. Hudec, University of Windsor.

EXPLORATION TECHNOLOGY DEVELOPMENT FUND

The following technology development projects pertaining to Southwestern Region received funding for 1985-1986:

Grant 051: Development of a Field Portable Technique for the Analysis of the Magnetite, Hematite, and Ilmenite Content of Basal Tills; W.A. Morris, Morris Magnetics Incorporated, R.R.#2, Lucan, Ontario.

Grant 077: Development of a Field Portable Instrument for Semi-quantitative Mineral Determination in Geological Materials; M. Shats, D.R. Gladwell, and M. Dancziger, Barringer Research Limited, Rexdale, Ontario.

Grant 081: Development of Interactive Software for the MAGLOG Small Diameter Borehole System; W.A. Morris and S.J. Balch, Morris Magnetics Incorporated, R.R.#2, Lucan, Ontario.

Grant 087: High Resolution Shallow Soundings Using Radar and Reflection Seismic Methods; J.L. Davis and A.P. Annan, A-Cubed Incorporated, Mississauga, Ontario.
